|Many thanks for all the comments. I am curious. What about the W2IHY
|Technologies 8-Band Audio Equalizer and Noise Gate that is advertised in
|QST. Will it achieve similar results as a good speech processor?

The short answer is NO.

But you can have endless fun on the air talking to others that are using them, particularly the guys that have bypassed the audio stages in the rig and are driving the balanced modulator directly.

"Okay, I've boosted 50 Hz by 1 dB and cut 400 Hz by 2 dB. How do I sound now."

"Just a minute, I recorded you... let me play it back."

"Hmmm. Well, I dunno... let me boost 50 Hz by another dB. How does that sound?"

"Oh, much better. Now try boosting 4 KHz just a bit...."

And the cell phone company thought they were original with, "Can you hear me now?"

You can also enjoy annoying the others trying to operate in close proximity, especially with the opposite sideband burble you're now transmitting as you attempt to extend your frequency response to 0 Hz.

No, I am not forgetting anything. The discussion had
nothing to do with an MOV that was not turned on. An
MOV that is not turned on does none of the shunting,
diverting or absorbing that is being discussed.
The equipment, prior to the MOV transition, "sees"
whatever voltage is on the line. That is irrelevant to
the discussion of the MOV in the low impedance state,
when it is absorbing the surge it "sees".

<snip>

>The voltage across it
> is not going to go much
> above the 300 volt turn on level so it does not dissipate much power.
> Not to say that they can't
> blow up from excessive dissipation.

Re: "so it does not dissipate much power"
It dissipates Isubt*300 if 300 is the clamping
voltage at that instant. The current ratings for typical
disc style MOVs used in point of use surge protectors are
from 125 amps to 7000 amps, depending on the size of the
MOV. That information comes from Panasonic - the url is:
http://www.panasonic.com/industrial/components/pdf/ZNR_APP_dne.pdf
So even a small one can carry 125 amps momentarily at 300
volts - that's 37,500 watts. Regardless of what happens
elsewhere, 37,500 watts is a lot of power.

>

> (lightning). Which does
> need to be passed to ground.

Tom said: "... Only true for differential mode surges which
typically don't exist. Destructive surges are typically
common mode."

Consider:
Lightning strikes nearby and causes a surge on the
HV line feeding your transformer. That creates a
common mode surge raising both the neutral wire and
the hot wires to some level above ground at the secondary.
At the service entrance panel, that common mode surge
becomes a differential mode surge, because the neutral wire
is bonded to the grounding electrode conductor in the panel,
while the hot wires are not. Thus dies the myth that
differential mode surges typically don't exist. Within
the set of surges that exists, differential surges certainly
do exist.

This subject is made needlessly confusing by
inaccurate statements.

You want effective surge protection on your AC wiring:
1) Have an electrician install a good surge protector in
the service panel with the best ground system practical.
2) Install name brand, relatively expensive (around $70)
point of use protectors with guarantees to replace the
equipment at stuff you can't afford to lose - like that $7,000
flat screen TV
3) Use a bunch of cheap protectors on other gear and
install a good protector on the phone lines.
4) Any other wire entering your house should not require
additional measures if it was properly installed.
examples - cable tv, satellite dish, tv or amateur
radio antennas

That's about the best a typical homeowner can do.

Thanks for the good suggestions. I'll order some.

The 2.5 mH RFC that I have examined is wound with a single conductor copper wire that I measured with a digital micrometer at 0.0062 inches in diameter, definitely not Litz. The insulation is green fabric, maybe silk or cotton. Whatever it is, the fabric insulation is deteriorating. I suspect that choke is 50 years old or more though.

Ahh...now it's all clear. Ken, I fear you've taken that formula so far out of context it no longer has meaning. It's from Dr. Koenig's letter to the editor, having to do with "how to get the highest Q out of a given piece of wire," and in no way is a formula to get inductance from just the number of turns and the winding pitch. In addition to that context problem, there are also, I believe, some problems in Dr. Koenig's basic premises. I didn't examine the whole letter in detail, but did see something similar from him in Electronics World, I believe, and he seems to go about it in a way that depends on a bunch of things that simply aren't true.

But the original article does have a definition of winding pitch that matches what Roy posted, and as I understand, "Radiotron Designer's Handbook" also follows the same definition. My reason for posting the original question was that I had found two independent pieces of software that used a different definition: pitch = length/(turns-1). One of those has since been reissued with what seems the more standard (and to me, correct) definition, pitch = length/turns. The programs I've found which do use pitch=length/turns give me inductance values which match very closely to what I actually measure for coils that I've carefully measured for diameter and length as well. For most of my work, the old Wheeler formula (L,uH = n^2*r^2/(9*r+10*l), where n is number of turns, r is coil radius to wire center, inches, and l is coil length to wire centers at end of coil, also inches) works fine...usually better than the 5% tolerance caps I have to work with...but there are programs that yield a bit closer values, and also estimate the Q, effective distributed capacitance, and both parallel and series self-resonances, and that additional info can be quite helpful too.

Cheers,
Tom

> believe they've reopened the business.

Yeah - but it's a bitch to do the mod right. You have to
change the 77's input to a Mic connector, then fashion a cable
for the output to connect to the rig. And you have to
mod the keying circuit to operate from the mic switch.
I must've done mine wrong. When I finished the mod, I
connected the new output cable from the Alpha to the mic
input on the 746. I fired up the Alpha and waited
a while - someone told me you're supposed to wait a few
minutes - then I keyed the mic. It blew the 746 right
off the operating desk - pieces of melted plastic
are still embedded in the sheet rock, according to
my wife. The carpenters have finished replacing the
section of wall that was destroyed, but they claim
they can patch the damaged sheetrock on the rest of
it. I'll be going back to the shack to figure out
what went wrong, as soon as I get these casts off and
the doctor gives me permission to walk up the stairs.
I'm sure the smoke odor will be gone by then.
We never did figure out whether the force of the
explosion blew me out of the chair and down the steps,
or whether I stumbled in the smoke and fell. The last
thing I remember is thinking how powerful my audio
was going to be.

Tom,

None of the basic solenoid inductance formulae I am aware of involve winding pitch.

Only length, diameter and a whole number of turns are required. These 3 values are necesary and SUFFICIENT.

So how come you get a difference in calculated inductance by entering a different value of winding pitch when pitch is not a requirement ?

9. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-01 23:16:57 UTC
From: w_tom <w_tom1@usa.net>
Message-ID: <3CF955E9.518FDA47@usa.net>
Source record: 43771

A common mode surge on hot and neutral, but earthed at breaker box on neutral is still a common mode surge. If it was 'converted' to a differential mode surge, then when it got to the equipment, any ground to that equipment would be irrelevant. Differential mode surges would ignore that earth ground. But the common mode surge only seeks earth back on the neutral if it cannot get to earth ground, destructively, through the appliance. The most important objective for that common mode surge (regardless of earth neutral) IS still earth ground - because it is still a common mode surge. Moreso, a 100 amp common mode surge that must find ground back at the earth grounded breaker box at 50 feet would leave the computer typically at less than 13,000 volts. Can't happen. Voltage too high. Any computer at 13,000 volts relative to earth ground cannot help but to find destructive paths, from input hot wire to earth ground through the appliance.

That common mode surge is not converted to differential mode if a neutral is earth grounded. Just like that common mode surge is not converted by the earth ground out in the utility pole transformer. That surge, arriving at the appliance on hot wire will find any or every earth ground - even if that path to earth is ground - because it is still a common mode surge.

Differential mode surges ignore paths to earth ground. Common mode surges will find earth ground, destructively through the appliance - as the definition of common mode makes extremely clear. That breaker box earth ground is electrically to far away to be all but no earth ground connection.

Again we return to a principal well proven and repeated demonstrated since the 1930s, repeatedly demonstrates in reams of IEEE articles, and demanded by serious surge protector manufacturers. Notice that ehsjr provides no references for his theory. At no time have any of the too many articles, applications noted, etc ever made a claim that grounding the neutral far from the appliance converts a common mode surge to differential mode surge. All incoming AC connects neutral to earth AND all professional papers still call that surge common mode. Again that well proven principal - a surge protector is only as effective as its earth ground.

What is the difference between brand name, plug-in surge protectors and no-name, less expensive surge protectors of same joules? The no-name, less expensive unit provides same, ineffective, surge protection for far less money. Components in that $70 brand name surge protector cost about $0.05 and $0.20 each. Where did the other $60 go? Into the name? Bonuses and stock options? Of course neither brand name nor less expensive surge protector is effective; made so woefully obvious because they must forget to mention critical earth ground. Without that short connection to earth ground, then the brand name, plug-in surge protector recommended by ehsjr can actually increase probability of surge damage even if the adjacent appliance is turned off.

Why? An adjacent surge protector simply shunts the surge onto all wires so the surge has more paths to seek earth ground, destructively, through the appliance. That is what a shunt mode surge protector does - distribute a surge to all other wires meaning that a common mode surge now has more destructive paths through that appliance. Plug-in surge protectors can make common mode surge damage more possible.

But this is the most damning fact. If those $0.05 and $0.20 components in that plug-in surge protector were effective, then they would already be in the appliance. They are not in the appliance because they are not effective in the appliance or in the adjacent plug-in surge protector. Are all appliance manufacturers that dumb? Of course not. They also know that the plug-in surge protectors recommended by ehsjr are ineffective - a waste of $0.05.

Any money spent on grossly overpriced, undersized, ineffective, plug-in surge protection is money wasted - that could have been used to make more effective 'whole house' protection. Money best spent is in enhancing that central earth ground network - the most critical component in any surge protection 'system'.

Forgotten in that third (of four) recommendation is that the phone lines already have superior, 'whole house' surge protection - if the homeowner has not compromised critical earth ground. Why is that phone line surge protector's earth ground connection so necessary? Because even phone companies know that their surge protector is only as effective as its earth ground.

There's a few shortwave receiver setups for PCs, I think one is actually
an internal board. But for transmitting, forget it. The RF power might
turn the PC to toast.
There's quite a bit of ham equipment these days that can be controlled
via PC.

"> Can anyone tell me if it'spossible to have a Ham Radio on a P.C.?
==========
Ten-Tec launched their Pegasus transceiver in 2000 . It is a box linked to the PC via a standard serial port permitting all operations from the PC's mouse or keyboard.
However I haven't seen their advertisments for this unit in QST lately.
Another US manufacturer Kachina had a similar unit before with even the mike /key connected to a module built into the PC ,but Kachina no longer manufactures that type of transceiver. Their seems to be no profitable market for this type of equipment

It seems that Hams prefer a stand-alone transceiver (probably having better specs) whether or not linked to a PC for certain modes or for automatic linking to the DX cluster , etc .

Have you tried a simple direct connection ? Unless the sound card insists
on having a balanced 600-ohm input a transformer is not needed.

If a transformer MUST be used just to convert from unbalanced to balanced
then any old ratio will do the job.

May work fine with just a length of wire plus a series resistor. There's far
too much waffle wasted on impedance matching. Who's interested in the
maximum power transfer theorem when all that's wanted is a few millivolts
and micro-watts.

>hot wire to earth ground through the appliance.

First of all, where does that mythical earth potential exist ? Did they keep in Sevre outside Paris as they did with the 1 meter stick and the 1 kg weight before changing the definition :-).

The oceans would be quite good to find a reference potential, but unfortunately the variations in the Earth's magnetic field will cause currents to flow and thus also potential differences to develop.

I don't know your wiring code, but that situation is not as bad as it sounds.

If you have a shunt between live and neutral at the equipment, the equipment could reach a potential several kilovolts above the mythical ground reference potential when a current surge occurred. As long as the equipment is isolated and does not have external connections, who cares at what potential it is.

Assuming a computer system including monitor, printer etc. are connected to the same grounded wall outlet. If the current surge is creating a high voltage drop in the neutral wire, any shunt arresters connected from live to protective ground and neutral to protective ground will conduct, effectively sharing the surge current from the outlet to the house distribution point. In your case the wall outlet would be about 6500 V relative to the mystical earth reference. However, the computer chassis, the monitor chassis, the printer chassis would all be floating at this same 6500 V potential so this should not be a problem as long as the computer system is not connected to the external world.

At least our wiring code recognises that there is no such thing as a perfect grounding, but requires that the electric system neutral (N) and protective ground wire (PE), central heating pipes, cold and hot water pipes, antenna masts are connected to a common grounding bar, to keep these systems at the same potential. This bar is then connected to a grounding electrode if the grounding through the cold water pipes are not sufficient.

If a large surge comes through the mains wiring (both live and possibly also neutral), the current will sooner or later end up in the ground bar and then into the grounding electrode. Due to the impedance in the grounding, the ground bar might reach a potential several kilovolts above the mythical earth potential. However, the cold and hot water pipes, central heating pipes and finally the house itself will reach that same potential. This should not harm the people inside the house, since they will also float to the same potential relative to the mythical earth potential.

While the computer system might be at a quite high potential, the plumbing and eventually the house is at a quite similar potential, so the potential diffidence is not that great as one might expect. The voltage difference between the equipment chassis and the piping is the voltage drop in the parallel connection of neutral and PE wire. Assuming there are multiple paths (other equipment) from the live to the grounding bar, the grounding bar will reach an even higher potential, thus reducing the current flow from the computer N/PE connection to the grounding bar and also reducing the voltage difference.

As long as the impedance from the wall outlet N/PE to the grounding bar is well below the impedance from the grounding bar to the mythical earth, the potential difference between the wall outlet and the house piping (and the house) is quite small.

While the perfect place for a surge arrester would be between the live and the grounding bar, a simple arrester mounted in the wall outlet is not in a hopeless situation as you are suggesting.

However, there is a snake sneaking into Paradise in the form of the telephone line (or serial or Ethernet cables to other buildings). The other ends of these cables are connected to a different grounding bar and a different grounding electrode. Thus, there can be quite a few kilovolts between the grounding bars in different buildings during a surge condition.

I have been working with various industrial control systems for a few years and there is often a need to transfer data to different buildings, some of which are quite old and the electric system is not in the best shape. In this situation it is more or less mandatory to use isolated serial connections. Building current loops with optoisolators is quite easy and the typical optoisolator breakdown voltage is 2500 V,which is usually quite sufficient, since there has seldom been any extended damage due to lighting. If a better isolation is required, optical fibres must be used.

The telephone line is a big problem, since both AC and DC information needs to be transferred (transformers and optoisolators), getting devices with sufficient isolation can be a problem.

I don't see a point of using elaborate grounding systems in the house, but one has to be very careful with any other wires (telephone, serial

data and Ethernet) coming into the house and use a high isolation barrier with these connections.

I have a spec sheet on the Sound Blaster and Sound Blaster Pro Family of sound cards. The line input impedance is 39K so a 600 ohm transformer is no where near matching impedances anyway.

I would just look up the design parameters in a good filter book like "Electronic Filter Design" by Williams. If you need flat, then use a 0.5db Tchebyshev or less, if not enough then a Butterworth. I have always had excellent luck using the Williams book for values. Using cascaded filters tends to pull the poles around unless you use a buffer between the two sections. The two corners are too close to one another at 2 MHz. Always remember, that a filter is nothing more than a properly designed mismatch, so impedance matters.

Filters are kind of fun. RF is a pain in the backend.

Anyone ever built a direct MOSFET switching CW transmitter here? Saw an article years ago, used a bunch of cheap High Voltage (800 Volt TV Flyback type) MOSFET's. VFO was entirely digital at the TX frequency, and drove the MOSFETs directly. Sort of Hyper Class C++ style. The output matching network took the edges off and probably had a Q of 20 or so. Low RDSon Power MOSFETs are dirt cheap these days and can be made to switch hard at least to 14 MHz. Efficiency should be 80+ percent (Low Heat generation), especially on the lower bands. Low switching losses are key. Probably a Full H-Bridge configuration is best, using all N-Channel MOSFETs. Power output is easily adjusted by varying the duty cycle of the drive. Add a transformerless AC power supply for 300 Volts or so, and voila.. worlds simplest and cheapest QRO CW transmitter. Legal limit will be less than 10 Amps which is easy to tame with a few of Digi-Key $3 power MOSFETs in parallel without that nasty huge copper and heatsinks common with those lower voltage linear MRF devices. Output Z of the xmtr should be easily tuneable with your standard roller inductor tuner which might serve as the output matching network depending on it's Q.

Any Thoughts?

The World will eventually become all Digital...

no, I have to mail it, is the address correct?

Just wanted to describe an application which wasn't supported by the
application note. The device was commonly available at low price and
suits my demands, mainly used together with an impedance bridge or
RLB. It is many better and later devices, you may even find an SMD
(which I don't like). Haven't checked overall performance yet, since I
had to mount it into a die-cast box first. Use a similar circuit with
MC3356 in my HF-rig for improved S-meter.

When I purchased a make APC UPS for my PC system 3 years ago I received a separate telephone line surge arrester with a short 'earth lead' . This lead is permanently connected to the 'earth'connection of a nearby wall socket (British 230V -50Hz wall sockets have 3 receptables :L-N-E) The arrester also has an in -and out telephone socket. I have no idea how effective these arresters are , but with overhead telephone lines in the area ,I have so far not experienced any failure of any equipment connected to the telephone line eg 2 phones , 1 fax machine ,internal PC -modem . Just for info.

> it [the transformer] is for protection, not matching.

Protection from what? One poster suggested that you would blow up the sound card if you didn't use an 8:600 ohm transformer to get a proper match. I've connected the line input of the sound card across the 8 ohm output of a receiver plenty of times without blowing anything and it always worked. It seems to me that adding a 8:600 ohm transformer will raise the voltage applied to the sound card, not lower it.

I agree that if the transformer is loaded with not less than 600 ohms it won't cause any problems. I'm just saying there is no need to match impedances (which you are not doing with a 8:600 ohm transformer anyway).

> mythical ground reference potential when a current surge
> occurred. As long as the equipment is isolated and does not
> have external connections, who cares at what potential it is.

is absolutely correct "as long as the equipment is isolated"
(the perfect faraday cage). But professionals are blunt - no
equipment is isolated. For example, that computer with an
adjacent plug-in surge protector has equipotential across AC
power lines. But the path to ground is through modem, network
card, or even through wires draped behind the desk on the
baseboard heat pipes. Real world surge protection
professionals repeatedly advocate, excessively, the central
point earth ground. If one has a problem with the concept,
then take it up with the long list of experienced
professionals and academic papers.

Furthermore, the most common reason for modem damage is an
AC mains surge that finds earth ground, destructively, via
phone lines. In the US, all properly installed phone lines
make a connection to earth ground. The connection will shunt
surges before entering the building - as every responsible
surge protector manufacturer advocates. But if the surge is
already inside the house - and especially if an ineffective
surge protector is adjacent to the computer, then a surge can
get out - destructively complete the electrical circuit -
using that phone line ground. Most modem damage is from AC
mains surges that force a computer to a voltage different from
earth ground.

To understand references, don't speculate about oceans.
First learn principals demonstrated and repeatedly proven
since before WWII. An example of the surge circuit is
demonstrated by Dr Richard Feynman in his classic three volume
set Lectures in Physics. But when it comes to surge
protection, one first learns what has been so proven in
history and electrical theory. For example, one professional
states clearly:
http://www.harvardrepeater.org/news/lightning.html
> Well I assert, from personal and broadcast experience spanning
> 30 years, that you can design a system that will handle
> *direct lightning strikes* on a routine basis. It takes some

> then connected to Earth through the lowest inductance
> connection we can make. What we've done is to create a single
> reference point for our station, a single point "ground".

Last summer, more experienced professionals noted same in discussions in the newsgroup rec.radio.amatuer.antenna such as Richard Harrison:
> Broadcast radio stations operate right through numerous
> lightning hits with few interruptions, much less damage.

Benchmarks in surge protection discuss same in wildly recommended application notes:
http://www.polyphaser.com/ppc_technical.asp

Before questioning my posts, one should first consult experience, papers, professional, and principals repeated demonstrated in IEEE publications, high reliability sites, from manufacturers who don't promote urban myths of plug-in surge protectors, or even why Ben Franklin's 1752 invention (air terminal or lightning rod) worked. It's all about the same thing - earthing a surge before through a safe, nondestructive path.

If plug-in protection is effective, then it costs about $1. But plug-in surge protection is more about hype. Not only is it undersized and mislocated, but it is also grossly overpriced at $20 or $50. That is 20 or 50 times more per appliance for protection only hypothesized as effective? Why is that plug-in protection such as smart solution? Its not. It's effectiveness is urban myth associated with reasoning that must ignore the realities of earthing.

Surges find so many paths to earth meaning that no appliance is isolated from destructive paths to earth ground. An appliance is protected when at the same potential as earth under the building. That so well proven and so less expensive concept is called 'whole house' surge protection. As Paul Keinanen notes, plug-in protection can be made effective. But who has the $thousand to hire those experts necessary to refine a sophisticated system around the computer? Furthermore, any wiring changes in that protected bubble may also destroy the protection design. The so well proven method

is always been central point earth ground, the single point ground window, the MGB, the bulkhead, ... so many terms because the concepts are so widely understood through the generations, and are internationally proven.

A belief that a philosophy student will protect his computer using a plug-in surge protector in any wall outlet only demonstrates the philosophy student first may need to learn the well demonstrated philosophy of "lying by telling half truths". However, maybe the student wants to spend more money, wastefully, for ineffective protection. We know there are many plug-in surge protector manufacturers who must forget to discuss earthing, so that the philosophy student will buy and recommend their product.

High isolation barriers don't exist in the real world. If a good isolation barrier existed, then lightning would not travel through an excellent isolation barrier - miles of air. Everything also has a breakdown voltage. Even linoleum tile and concrete floors can become a good surge conductor. No way around a most effective surge protection concept - central earth ground determines the effectiveness of a surge protector - series mode or shunt mode. High reliability facilities cannot get a central earth ground that is good enough because central earth ground is what makes better surge protection.

If a plug-in surge protector was so effective, then all appliance manufacturers would install those $0.05 devices. They don't, because it makes no sense to waste only $0.05 on such ineffective protection. A surge protector is only as effective as its earth ground.

Never heard of static discharge? Or lightening? Or just voltage
differences? Once damaged the motherboard with a cable connected to
the PC's serial port, but removed from the TNC. The lightening stroke
a half mile away just as I shut the door to go to work.

As I mentioned before, a friend learned from damaging the sound-card
as he tried to connect it to the transceiver, it was some voltage
difference

Another advantage with the transformer is to avoid hum induced on the
line.

Ignorant amateurs often never learn before the damage has been done a
few times, some don't. This was more commonly experienced with the
Commodore computers we used two decades ago because of less protection
of the interface. The most common way to sort this out was to use
opto-couplers between the computer and modem. But the problem still
exists, but the PC is somewhat better protected.

The balance adjustment is to change the DC bias on the input pin of the 74AC86 so that the imposed AC sine wave will cause the part to toggle as it passes through the '0' crossing of the sine wave.

This toggle point will vary a bit as the component warms up, but the fixed adjustment is about as good as any way to use this part as a converter from sine wave to square wave.

==========

The alternative would be to double the frequency and then use a flip-flop to divide by 2 and get the 50% duty cycle LO drive for the mixer.

This method removes the finicky analog adjustment, but it also requires a pretty fast divider chip, depending on what your LO frequency is.

Fairly simple to do up to 30 MHz or so, and it makes the mixer circuitry less sensitive to temperature affecting the LO duty cycle.

Well, I have had customers damage equipment due to AC ground loops from
time to time.

If they had used the recommended connection then an transformer for
isolation purposes would have protected the input they were connecting to.

Granted, this was overseas and on some areas the ground on the AC line
leaves something to be desired. This made it more likely to have a high
ground loop potentual, but it happens everywhere.

Most of the time, one can direct connect and get away with it depending on
the quality of the AC lines, earth grounds, Etc....

But all in all, an audio transformer is cheap insurance.

Hi folks,
I've been feeling creative lately, and have been thinking about developing a series of high performance kits, including receivers, preselectors, etc. Let me know what any of you would like to see, and maybe I could develop your idea along. The approach that I am thinking of taking is to make the printed circuit board and the parts available, and leave it up to the builder for packaging in the enclosure. Interested parties can e-mail me directly.
Thanks!

I seriously doubt that a little audio coupling transformer is going to protect the input to the sound card from lightning. I'll stand by my statement that unless you have some really serious grounding or electrical problems you are not going to damage a sound card line input by connecting it to a scanner's speaker output.

Hello all,

The one transistor FM receiver (super-regenerative),
now has two websites. If one is disabled, chances
are the other is not:

If you are new to this receiver, please take a
look at it. It is by far the simplist one I have
ever made. The sensitivity, selectivity and great
audio output is what you will expect, once your
journey has come to the end.

I call is "The Radio Shack Special", since all
of the parts may be
purchased there.

>snip
> Have you ruled out the use of an umbilical cord to carry comms (and
possibly power)?

On top of that, the umbilical is a safety line if the little guy stops responding to commands "at depth". You don't have to strap on a set of tanks, or kiss the investment goodbye, or hope that the failsafe positive buoyancy works (you did include something in the design where if you lose power, the bot floats to the surface, didn't you ???). You just have to pull the darn buggy thing back up.

Whatever wiring you use to carry data and especially with power, make sure it's rated for underwater use, not just "water resistant", although fibre optical doesn't have that kind of problem. Then wrap the umbilical together with a strong rope or cable (depending on the size of your robot) so that any towing or pulling doesn't put any weight on the wiring, just the load rope. You might try using nylon rope like is used for ski-boat tow handles, because it floats, and depending on the weight of the data cable or fibre, may make your umbilical neutrally or positively buoyant. At best, look at this rope and check out the outer braiding. Do something like this to wrap your entire umbilical to help prevent damage and/or snags. Another idea, although expensive, would be the kind of rope that is used by rapellers or rock climbers (although if I remember right, that kind of rope is cloth based and would not only rot easily underwater, would need to be completely dried after each use). Ok, never mind the rock climbing rope, but the same idea stands. The load bearing strands are sheathed in a protective outer braid to make the rope more manageable and avoid snags.

> is absolutely correct "as long as the equipment is isolated"
>(the perfect faraday cage). But professionals are blunt - no
>equipment is isolated.

I assume we are discussing mains conducted over voltages and not direct lightning hit to the power pole next to the house. In the latter case I very much doubt that even large spark gaps would protect the equipment, no matter where it is installed inside the house.

>For example, that computer with an
>adjacent plug-in surge protector has equipotential across AC
>power lines. But the path to ground is through modem, network
>card, or even through wires draped behind the desk on the
>baseboard heat pipes.

As I later pointed out, modems need special protection.

The network card is not a problem as long at is connected to an other computer in the same room from the same wall outlet.

Flash overs to metal structures 30 cm to 1 m away will only occur, if you have a direct lightning hit, in which case I guess you have other things to worry about.

> Real world surge protection
>professionals repeatedly advocate, excessively, the central
>point earth ground.

Equipotential bonding is a good thing, but when the resistance to the real earth might be 10 ohms of more, a surge of 100 A will increase the potential of the main earthing terminal and all equipment connected to it to 1 kV, a surge of 1 kA to 10 kV and so on.

>If one has a problem with the concept,
>then take it up with the long list of experienced
>professionals and academic papers.
>
> Furthermore, the most common reason for modem damage is an
>AC mains surge that finds earth ground, destructively, via
>phone lines. In the US, all properly installed phone lines
>make a connection to earth ground.

At least previously here in Finland, it was forbidden to install surge protectors in to phone lines that had a connection to the earthing system. With large potential differences between buildings, quite high

currents would flow in the telephone cable, melting it. I do not know the current situation, but I guess that due to much damage to answering machines, faxes and modems mainly from the Far East (with inadequate isolation), this policy may have changed.

>The connection will shunt
>surges before entering the building - as every responsible
>surge protector manufacturer advocates.

Yes, it would preferable to have spark gaps in the utility pole _before_ the mains wires enters the house, in which case it would even giving some protection for direct lightning hit to _that_ pole. However, that would require grounding each pole.

> http://www.harvardrepeater.org/news/lightning.html

Gary here describes the grounding window, which is a form of equipotential bonding. When there is a surge, _every_ equipment within the building floats up to possibly several kilovolts above the ground potential of the neighbourhood, due to finite grounding resistance (impedance) in any practical installations. Thus, any other building with a similar grounding will have a different potential during the surge.

It should be noted that while grounding windows will protect the equipment inside it, it does not allow data communication while the surge arrester is operative. If the communication must work even during this surge period, the only thing to do is to use sufficient isolation (such as fiber optic cables) and avoid arrestors from the data line to the ground.

> Surges find so many paths to earth meaning that no appliance
>is isolated from destructive paths to earth ground. An
>appliance is protected when at the same potential as earth
>under the building.

It protects the equipment within the house, but when the house and the surrounding garden gets into an elevated potential, which is different from any other buildings in the neighbourhood (including telephone exchanges).

>Furthermore, any wiring changes in that protected bubble may
>also destroy the protection design.

Any new wire (e.g. Ethernet to the neighbour) might not be properly connected and protected to the grounding window, destroying the protected bubble :-).

> High isolation barriers don't exist in the real world. If a
>good isolation barrier existed, then lightning would not
>travel through an excellent isolation barrier - miles of air.

Talking about over voltage protection for mains connected equipment and protection against direct lightning hits in the same sentence can

be a bit misleading :-).

High isolation barriers sufficient for most practical situations can be made with optical fibers. The additional benefit with fibres is that they will operate during the surge, which can be quite critical in some industrials installations.

Having already built one of Pete's hi end receivers
(http://www.parelectronics.com/pix/Pg150.jpg

(and using it more than ANY of my other receivers) I can tell you, these will be
1st class. Pete, from reading mail on the shortwave reflector, there seems to
be a goo deal of interest in passive preselectors- perhaps using soft switching
as in the Lowe model that goes with the HF-150.
Thanks for a great RX design.

It's a little away from ham radio, but I think that a high quality FM-broadcast tuner would be a huge winner. The designs used in mass-market receivers really stink compared to the discrete designs of old, and the high-end stuff is unapproachable for most mortals. The Tivoli design with its GASFet front would seem to be reminiscent of technology used for 2m and above. I think a kit like this would sell in the tens of thousands of units.

But lightning is a high frequency event. That outlet ground is how many meters to earth? Wire impedance - not wire resistance - are the critical numbers. Wire is an electronic component of the surge protection 'system'. That outlet ground is therefore called a safety ground - not earth ground. A phone line surge must also find other paths to earth because outlet to earth connection is too far.

http://www.telebyteusa.com/catalog/appnotes/a22px.htm demonstrates how phone line protection must be installed. The path to earth ground must be many times more conductive than the destructive path through electronics to avoid electronics damage. That phone line protector must be closer to earth and far from the appliance to be effective. In the UK, I am told that a type of master socket, called NTE5 has an earth grounding stud, but that most don't connect it. However the UK has so little CG (cloud to ground) lightning compared to the rest of the world meaning that some modem damage is acceptable?

APC, Belkin and other retail names are not quality surge protectors. They are overhyped, overpriced, and undersized. Made obvious by their total avoidance of earthing discussions. Instead, look at a benchmark. Their customers must never suffer damage from a direct strike. Therefore their application notes discuss earthing extensively. http://www.polyphaser.com/ppc_technical.asp

APC, et al is selling to the naive. Even their joule ratings are undersized. Professionals say distance to earth, splices in wires, ground wires through metallic conduit, multiple grounds, and even sharp bends all affect surge protection 'system' performance. Those selling ineffective plug-in protection never mention those critical parameters and avoid any discussion of what lightning really wants - earth ground.

Surges typically occur once every eight years. In the UK, such events are even less frequent. That statistic makes any recommendation based upon 'no damage yet' unreliable and misleading. 'No damage so far' is the sort of reasoning that overhyped plug-in surge protector would encourage to increase sales of their ineffective products.

Most often ignored is why earthing must be 'central' earth ground. Learn why in those above cited application notes.

There is no reason to believe any direct strike must damage. It is urban myth that lightning is a high energy event. Alan Taylor of the US Forestry Service demonstrated that most trees - well in excess of 90% - struck by lightning leave no appreciable damage.

From Colin Baliss "Transmission & Distribution Electrical Engineering":
> Although lightning strikes have impressive voltage and current
> values (typically hundreds to thousands of kV and 10-100 kA)
> the energy content of the discharge is relatively low ...

Only failed surge protection systems do not protect from a direct strike at the pole. That includes modems, portable phone base stations, and fax machines. They all are included and protected by the same 'system'.

Every wire entering the building, including phone lines, are connected, either directly or through a surge protector, to central earth ground. That means a wire between buildings is earthed at both ends. This was a problem in the early days of Arriene rocket launches in French Guiana (I know I trashed the spellings). Proper earthing procedures at each structure were not followed resulting in computer damage.

Yes, earthing potential will rise because the earth is not conductive enough. We earth to make soil under the building equipotential. But earth cannot be equipotential enough across the building. So we try to dump all the surge into earth before it can enter the building at a central ground. But again earth cannot be conductive enough to absorb the whole surge. So we make the soil under the building more equipotential.

IOW we do both because neither is sufficient. Both means using central earth ground AND making the earth ground network beneath the building superior. However even a single ground rod in conductive, unfrozen soil can provide major surge protective benefit.

'Whole house' surge protection is called secondary protection. Primary protection is a ground that connects pole transformer to earth ground. Not a ground on every pole - but the critical one connecting transformer to earth. That utility pole ground is important for household surge protection from a resulting 'power follow-through current'.

A surge may create noise during the event. But the event is typically tens of microseconds. Furthermore, all communication must have error correction or other redundancy. Should fiber optic be necessary, then this communication line is so critical that a 30 microsecond loss of data is $hundreds. Small facility don't require that kind of reliability.

But fiber can solve another surge problem. We have only discussed the science of surge protection. Geology, for example, turns the science into an art. If geology makes equipotential impossible, then yes, fiber may be the expensive, more acceptable solution. IEEE Transactions are full of papers whereby professionals apply extravagant solutions to facilities that were properly installed but still not sufficient.

If incoming wires enter the building from different locations (cannot share a common bulkhead ground), such as "(e.g. Ethernet to the neighbor)", then more expensive solutions are required. One solution is to replace copper with fiber. But for most facilities, copper is more than adequate IF care is taken to implement the science of surge protection - especially central earth ground.

That ethernet to a friend's house provides isolation barriers of typically 2000 volts. But potential differences between homes during a strike can easily exceed that isolation barrier. The 2000 volts is sufficient if wire is earthed before entering the building but is insufficient if two buildings take on different voltages during a surge.

We have said much the same thing however I hope to have added a few new ideas such as the pole transformer ground and making sure earth ground remains below the frost line.

All buildings have neutral earthed at the main panel. And yet still professionals discuss the common mode surges that enter those buildings. They don't discuss converting common mode surges to differential mode because that conversion is only your speculation. A common mode surge on the hot wire arrives at the appliance still as a common mode surge - regardless of what happens on any other wire such as the neutral.

Surge protection is about earthing a common mode surge before it can enter the building. But plug-in surge protectors can contribute to damage even to a powered off computer. The surge is provided more possible paths to earth, destructively, through the adjacent appliance by the plug-in surge protector. Therefore plug-in surge protector manufacturers simply forget to mention earth ground or even mention what a common mode surge is. No sense providing information a customer can use to see them as ineffective.

If earthing a neutral converted common mode surges into differential mode surges, then appliance manufacturers would routinely install those $0.05 and $0.20 parts inside appliances. Those parts are not installed because they are not effective. Why then would they ever be effective in a power strip? Common mode surges are not converted to differential mode by earthing some other wire far away. Common mode surge arrives on hot wires to damage an appliance. No plug-in surge protector is going to change that fact which is why money is best spent on enhancing the 'whole house' surge protector system.

The tuning knob lacks friction and doesn't turn the dial. It's a friction drive but I don't know what the problem is. Is there a rubber tire that is missing? It looks like brass-to-brass and that doesn't make sense. But I can't see where a rubber tire would go.

Help please; I don't have a manual. Most manuals wouldn't show an exploded view of this complex mechanism anyway.

Bob

But I can show you trees in my yard that have the bark stripped off top to bottom. Some have died. I also had an experience in Jacksonville, Fla where the copper disappeared from the inside of the phone wire (pole to pole) while leaving the insulation in tact - still connected to the poles but sagging to the ground. I also helped a friend remove what was left of his aluminum tower after the legs were blown open (inside to outside) on nearly every 10 foot section. We assume that the air inside the legs must have been heated and expanded so rapidly that the tubing burst open.

I imagine what happened to your friend had more to do with high-power RF
getting back into the sound card via the line-in jack than any audio
signal-level or impedance-matching issue. He must have had a bad case
of "RF in the shack." I used to see this happen a lot when writing
CW-reading software for my Apple][back in the early 80s.

You're right, in that an audio transformer would probably have prevented
the damage... just not in the way that you're thinking. Better to
identify and fix the underlying cause of the overload damage.

> different value of winding pitch when pitch is not a requirement ?

Hi Reg,

Well, since I don't have the source code to the programs I was
testing, I really am not the one to answer that question. I can only
tell you that with ONE of the programs, at least, I could adjust the
pitch to get to an indicated length that matched what I expected for
the given number of turns, and in so doing, I got results from the
program which matched much more closely the inductance that I measured
for a small number of test coils.

I suppose that program simply calculates the coil length from the
pitch and number of turns, a very reasonable thing to do since it
displays the calculated inductance (and other parameters) for several
consecutive turns counts, for a given pitch. Also, it matches the way
I wind coils: I don't try to put n turns in length l, but rather wind
n turns at a particular pitch determined by the spacing wire, or by
the screw thread on which I'm winding it, or by the feed rate of the
lathe I'm using. I happen to find that program very convenient when I
am trying to figure a practical way to realize a certain inductance,
and now that it's been corrected to give the correct length for a
given pitch and number of turns (and correspondingly, an apparently
more accurate estimate of the inductance), it's actually useful to me.

I'm hoping to find time to test a wider range of coils; perhaps I'll
also test the self-resonant frequency as well. It would be nice to
know that the limited tests I've done weren't just a fluke. I'm
thinking of testing coils which are relatively short and relatively
long, and wound with wire which has a diameter much smaller than the
coil diameter, and wire which has a diameter which is a significant
percentage of the coil diameter. I will also try to arrange to make
accurate inductance measurements at both low frequencies (perhaps
10kHz) and in the HF range, though of course to test at low

frequencies accurately, I'll need enough inductive reactance to make it practical. Comments on choice of test cases are welcome, of course, though what acutally gets tested will depend on my supply of "round tuits". Also, I'm aware that others have done similar tests in the past, and if anyone can supply references to what appear to be accurate measurements of coil dimensions and inductance, I'd be grateful for that help as well.

Cheers,
Tom

Cheers,
Tom

I can't say enough about those application notes from
Polyphaser.
http://www.polyphaser.com/ppc_technical.asp
Sometimes they become difficult to read because of nouns
used. Best to first learn what the noun means, then reread to
understand the concepts. For example, the single point earth
ground may be called a bulkhead.

Homes and factories are equivalent to radio stations.
Whereas radio stations have antenna, those other structures
have same in the form of AC electric (highest on the pole) and
other incoming utilities. Same principals of surge protection
apply to both.

Also for background reference is the IEEE Transactions on
Electromagnetic Compatibility for 4 Nov 1998 which was totally
dedicated to this topic. Notice that all surges, even
induced, are considered the result of a direct strike (as
demonstrated by figures). Surge protection is about avoiding
damage from direct strikes. Those IEEE papers can be
difficult to read. But the figures and overall concepts point
to the same principals of central earth grounding and other
events related to that fundamental design - such as an induce
surge in a wire adjacent to one carrying the surge.

For examples of better earthed systems, see

http://leminstruments.com/grounding_tutorial/html/index.shtml
especially the example for a Cell Phone Station. That is a
complete 'system' for high reliability operations. But we
want to install stripped down versions of same in any building
with transistorized appliances. Although they don't discuss
it, the easiest and one of the most highly regarded grounding
methods is Ufer grounding. Ufer grounding exists in most all
new buildings, but we still don't use it.

Although the NEC does not address surge protection issues,
they do define minimal requirements for how grounding must be
installed.

If you have that many examples of rare hot lightning, then imagine how many more surges you may have suffered without detection. Also lightning may not strip the bark. Lightning may be the spark plug that ignites a more powerful fuel such as tree sugars which in turn convert water to steam - enough energy to blow bark off the tree.

In that previous post, Colin Baliss goes on to discuss where destructive energy comes from. For example, in a house where wires were blown out of the walls, lightning typically does not have sufficient energy. However the utility does. It is why the pole transformer ground is so critical to household surge protection. Should lightning create a plasma conductor from 13Kv or 33Kv primary to 240v secondary feeding the building, then long after lightning has terminated, the utility is pumping high voltage into the building.

As Colin Baliss writes:
> ... the energy content of the discharge is relatively
> low and most of the damage to power plant is caused by
> 'power follow-through current'. The lightning simply
> provides a suitable ionized discharge path.

Rather surprised that the aluminum legs were sealed. I would have expected them to have substantial breathing just to eliminate humidity problems. Too much moisture could even result in damage from freezing puddles (elsewhere). You are describing a region that averages maybe 6 to 12 strikes per sq km per year - variance higher (or lower) across the county. It is why good earthing (and sandy soil is a worst earthing) is so important.

The way you argue, anything would really have helped. A resistor in
series with the line is another very simple, but often effective way
to limit all sorts of accidental discharges, it even may prevent RF
from causing problems, but not hum pick-up.

I don't know the set up on the SP600 but when I bought my HP freq. Generator
the shaft was froze to the bushing as it went through the front panel. I
disassembled, cleaned and lubed it
then the tuning adjuster had more friction than the tuning capacitor,
and everything worked well.

I think Jim's analysis is fine. I'd like to offer another way to
implement essentially the same circuit so it auto-adjusts.

If the 74AC86 output really drives to the rails, within a few
millivolts, then you can detect the duty cycle as the average level of
the output. When it's at 50%, the average voltage will be 1/2 the
supply voltage. So, if you bias the (+) input of an op amp integrator
with a (precision) 1:2 divider from the supply, and drive the (-)
input with one of the outputs through a large resistor, the integrator
output can then be used to drive the input stage's DC bias, and it
will keep the output duty cycle constant.

If you are driving a load that keeps the 74AC86 output from going to
the rails, you can likely use a buffer...or monitor the drive to the
output stages. You can put a trimmer in the 1:2 divider to trim
things up slightly, but still benefit from the feedback tracking which
should do a good job keeping it constant over things like temperature
variations.

You can also do some more fancy things like monitoring both outputs
and using the op amp to servo them to be the same duty cycles, even if
both are slightly different from 50%, if it's worth the effort. So
long as the outputs go to equal loads, then even if the output levels
don't go to the rails, you still get very close to equal output from
both sides.

Cheers,
Tom

One think that I have had in the works for awhile has been a good FM tuner design, using a doubly-balanced mixer. I am not sure if I am going to go with a single or a dual conversion design. The hardest things to get ahold of are the TDA1591 multiplex decoder chips and the Toko ABW07-3618 19kHz/38kHz filters. Using my McIntosh MR78 tuner as a test bed, I have had good results. Over most of the audio range, stereo separation is 55dB, and stereo distortion is .08% @ 1kHz. If I can get a line on some of the critical compononts in any quantity, I will definitely persue the endeavor.

Quick fix is to use a bit of bee's wax on the drive wheel. It provides
enough friction to allow turning of the cap. Also works fine on dial
cord radios where everything has dried out after years of little use.

Good luck

A TI 74HC4066 has ON-resistance of 15 ohm typical, see
http://www-s.ti.com/sc/ds/cd74hct4066.pdf while Philips 74HC4066 has
20 ohm at 9V supply, see
http://www.philipslogic.com/products/hc/pdf/74hc4066.pdf

You normally connect two and two switches in parallel, then you have
typical resistance of 7.5-10 ohm, and it has only academical interest
to choose at better device, particularly when the better device is an
SMD type which isn't very much suitable for amateurs using dead-bug
mounting method.

The CD4069UBE buffer draws 10mA@10V, not certain if the 74HC86 will
draw more current on 9 or 10V. This may work with -10dBm oscillator
level (-30dBm on 200kHz), so I still believe the HC4066 is the right
device to choose for QRP up to 7MHz. Believe the HC86 stage is
described as 74ac86.jpg (never understand why somebody scan and save
as jpg when gif makes much smaller file size and better readability)
at http://www.geocities.com/CapeCanaveral/Lab/9595/fst3125.html .
DL7JGR's notes will give some valuable information to simplify the
construction, but I suspect he looses some gain in the front-end, it
is fairly easy to make a construction with -120dBm sensitivity, at
least it worked for me on 136kHz to hear a signal down below -126dBm
with no RF-stage ahead of 74HC4066, and otherwise quite similar
construction to what I would have used on 7MHz

It is so easy to wind your own transformers, so I don't see the point
in using MCL, they probably saturate long before the mixer.

One problem remain. Since everybody is only concerned about using 50 ohm, I have a problem finding suitable 200 ohm termination amplifier designs. Suppose it isn't just to use a lower gain JFET or J310 with low current, hi

The beveled wheel that turns the dial plate is kept pressed up against
it by a triangular plate mounted to the front of the chassis on 3
floating mount points, with an "S" shaped spring to keep tension on.

In my SP-600, these 3 floating mounts had become locked in place by
dirt, etc. A complete cleaning fixed the problem.

And where does one get beeswax? Would something else work as well?

I don't think the mechanism is sticky at all. It's just that the brass is too smooth and there is no grip.

I tried some of that non slip goop and it didn't help at all; that's intended for dial string anyway.

It occurred to me to put some solder on the brass but that wouldn't last long and might cause trouble that I won't be able to undo.

I have cleaned and cleaned and even stretched that spring that pushes on the idler shaft and it's still very flaky in tuning.

The floating mounts are okay; the idler is free to move on them and the S spring is working. I even stretched it a little. I cleaned and cleaned. Still not enough friction.

I am loath to try to reduce the friction in the mechanism, since it doesn't appear to be binding and I have been warned not to add any lubrication anywhere.

I will clean some more.

It is usually moisture that gets turned into superheated steam that causes trees to explode or the
bark to be peeled off when lightning strikes.

Wire can be easily vaporized by high currents from lightning. Sometimes while vaporizing it will
explode and scatter particles everywhere. The same thing happens if you use a 12 volt rated
fuse in a 120 volt circuit. The fuse can explode when it blows.

Usually when tower legs split from a lightning strike it is because there was water trapped in the
leg. The high current causes it to turn to steam and the steam splits the leg.

It is very rare for lightning to go through a pole transformer. It does happen with very large
strikes at times but most of the time if lightning hits the main lines it never makes it through the
transformer. Some amount of energy gets through from capacitive coupling within the
transformer but it is greatly reduced. The transformer will saturate with high voltage and limit the
magnetic coupling . Most damaging lightning that comes in on the power line comes from
lightning hitting the secondary line between the transformer and the building. Sometimes large
currents can also be induced into the secondary lines also from other nearby lines that may be
carrying the strike. If you have long runs of secondary line from the pole transformer (120/240)
you will probably have more problems with lightning coming in on the power than if there is not
much secondary line from the transformer. Sometimes it parallels the high voltage lines for a long
distance.

Even underground telephone lines have gotten high surge currents induced in them from
underground utility lines that carried a strike.

The thing to remember is that all lightning strikes are not mega strikes that cause severe damage.
There are many lower level lightning strikes that happen that never cause any damage.
Sometimes these smaller strikes do some damage that is not

recognizable as a lightning strike
and is blamed on some other cause for equipment failure.

It seems like the problem with most FM BCB receivers is that they are too sensitive. I once had a Sony receiver, from about 1970, that was quite unsensitive and had no rf stage, but it didn't suffer from overload like a lot of receivers I've tried (admittedly nothing high end). Since the sensitivity isn't needed in most use (because people are only listening to local stations), they might as well get better signal handling capability. Of course, then the sensitivity spec would look bad.

I've picked up a number of Delco digitally tuned car radios (I'm not sure where to look for the part number) for five dollars each at garage sales, and I'm impressed by their FM BCB performance. It looks like they use some sort of transistor in the RF stage intended for the purpose (if I remember, the package has four leads coming out from the center), and then into an IC that has a Delco part number but which I assume is a double balanced mixer of some sort. The limit I'm finding is that I need to change the IF filter in order to get distant stations adjacent to local stations.

But I too have thought about making an FM BCB receiver with the same sort of designing that goes into communication receivers. Of course it would use a diode mixer, and I think I'd start with that, and have whatever ahead of it plug in. Get the IF strip going, I think the real problem would be getting the IF filters, especially so you could have different bandwidths.

If I was going to double conversion, I'd put the IF high enough in frequency so the image rejection of the front end could be reduced. Maybe one could use an SAW filter out of a TV set; sort of wide, but available.

In some ways, it stops there because I wasn't sure what I was doing with it. There was a time when I wondered if I could receive a not quite local station, and I thought a fixed tuned receiver (maybe helical filters at the front) and a crystal controlled local oscillator might be interesting. Or maybe a combination, make it tuneable but allow for switching to a fixed frequency front end for a station (or maybe two) that I really wanted.

But even apart from weak signal use, there are different FM detectors that would be interesting to try out. A pulse counting detector, like a Heathkit once used, has always intrigued me.

Somewhere, I have two articles that popped out of a stack of "The Journal of the AES" that deal with improved stereo demodulation. I haven't seen them in some years, so this is vague. One dealt with using a non-square wave for the regenerated stereo carrier, I think it used Walsh functions. The other used some scheme based on pulse counting, but dealt with deriving the two stereo channels more directly. I must think about where I put the articles, because they were interesting, and covered areas that I hadn't seen elsewhere when it comes to stereo decoders.

Hello,

These valves are completely new, never used. They are in original
boxes and in mint shape. The valves are mostly HALTRON brand, but
they were a typical 'rebranding' company and got their valves from
well known manufacturers like Philips, Mullard, Siemens etc.

The following are for sale. The price shown are for each valve, and
as you can see, they are very low.

950 pcs DY 87 $ 0,40 HV single rectifier

60 pcs EB 91 $ 0,50 = 6AL5
40 pcs EF 50 $ 0,40 WW2 wideband pentode
20 pcs EF 55 $ 0,50 WW2 wideband radar pentode
200 pcs EF 183 $ 0,50 = 6EH7 remote cutoff pebtode
40 pcs EY 81 $ 0,40 Booster diode 550V 150mA
40 pcs EY 86 $ 0,40 HV single rectifier

220 pcs PABC 80 $ 0,50 triple diode + medium u triode
400 pcs PC 900 $ 3,00 high gm VHF triode + audio
90 pcs PCC 85 $ 0.40 double triode VHF
280 pcs PCF 200 $ 0,50 triode + high gm pentode
350 pcs PCF 201 $ 0,50 Triode + high gm pentode
630 pcs PCF 801 $ 0,50 Triode + high gm pentode
370 pcs PCF 802 $ 0,60 Triodepentode
730 pcs PCH 200 $ 0,50 Triodeheptode

150 pcs PCL 81 $ 0,60 Triode outputpentode
190 pcs PCL 82 $ 0,50 Triode outputpentode Wa 7W
200 pcs PCL 86 $ 0,60 Triode outputpentode Wa 9W
250 pcs PFL 200 $ 0,50 Pentode + high gm outputpentode
(S= 22mA/V Wa 5W)

100 pcs PL 36 $ 0,50 Line outputpentode Wa 12W
170 pcs PL 82 $ 0,50 Output pentode Wa 9W
170 pcs PL 83 $ 0,50 Output pentode Wa 9W
360 pcs PL 84 $ 0,50 Output pentode close to EL 84 l
200 pcs PY 81 $ 0,40 Booster diode 550V 150mA
100 pcs PY 83 $ 0,40 Booster diode 175mA

Even more discount is available if you buy large quantities.

>single point earth ground may be called a bulkhead.

Now might that be a clue about your own highly individual use of the nouns "earth" and "ground"?

The reason Polyphaser call it a "bulkhead" is that they're referring to a physical plate through which all services must pass, and be bonded to equalize their potential in common mode. And the reason they don't call it an "earth ground" is that it is neither earth nor ground.

The "bulkhead" system of equipotential bonding works well, if it's designed and installed correctly. It's useful to consider how this system works, in order to see how household installations fall short - especially if there's a ham in the house.

For example, in broadcast transmitting stations, the "bulkhead" system allows uninterrupted operation (or very nearly) even during a direct strike to the tower - which may happen several times a year. Every electrical cable entering or leaving the transmitter building passes through this bulkhead, and its ground conductor (if it has one) is bonded to it. Conductors that cannot be directly grounded - like the phone lines and the inner conductors of coax cables - are protected by surge arresters that are bonded to the bulkhead; these protect against differential-mode surges appearing at the equipment input/output ports.

The bulkhead plate is also bonded to a very effective earth system - and by earth I really do mean "true dirt". The purpose of the earth system is to provide a path for the lightning current that does <not> pass through the installed equipment in the transmitter building. Because of the resistance and inductance of the earthing system (including the dirt itself), the whole of the bonded installation in the building will "bounce" with respect to ground potential (whatever that may be at the time of the strike) - but that doesn't matter because it's all in the same equipotential "bubble".

Bottom line: if equipment does not experience large surge voltages and currents <inside of itself> it won't be harmed.

The only limitation, as other people have mentioned, is that the equipotential bubble (nice expression, that) must not be punctured by any other incoming current path. At the design stage, this is ensured by

allowing no conductors to enter the building by any other route than the bonding bulkhead. In addition, it's necessary to ensure that no new current paths through the equipment will be created during a strike, due for example to an insulation breakdown, a side-flash through air, or a potential induced magnetically from the huge current pulse flowing in the earth conductor. An effective earth system can ensure that the protected equipment doesn't "bounce" too far with respect to its surroundings, and careful system layout can prevent side-flashes and induced potentials.

That description is of a purpose-designed industrial system, where the designers know that lightning strikes <will> happen, several times a year, so they have to get it right. We all seem agreed that, compared with this ideal system, most household systems are very poor.

Household systems have nothing resembling a bonding bulkhead, or the discipline of bonding all incoming cables to it - and once again, I do mean <all>. Electrical wiring codes generally require some form of equipotential bonding of power ground conductors for routine safety purposes, but there's no way this meets "industrial" lightning protection standards. As already noted, other services such as phone and cable may or may not be bonded to the power ground. Surges can thus get into household systems via any one of the connected services. Once they're in there, very large potentials can develop between different parts of your household electrical system - and that's what kills electronic equipment.

Hams make things even worse by erecting large arrays of lightning attractors, establishing extra earth (and again, I mean true dirt) connections outside of the house, and bringing them all indoors via antenna and rotator cables. Wiring codes may require bonding of all "earthed" electrodes, but these are only for routine shock protection. If there is a nearby lightning surge that creates a significant potential difference between your house electrical earth and the radio earth out there in the backyard, the "earth bonding" and your radio cables are a highway that brings destructive surge currents into the house.

A fortunate few hams, when building a new home in a lightning-prone area, have been able to have all services brought into the building at the same location, where they can be bonded together and to an excellent earth connection. Then they can route all their outgoing radio cables through the same location, and bond them too. Along with this single-point bonding goes an array of differential-mode protectors for conductors that cannot be bonded to ground. That goes a long way towards the industrial-type system, and protection will be good unless some other incoming wiring breaks discipline and bypasses the bonding.

The rest of us, in less lightning-prone areas and with household and ham wiring that has "just growed", just have to do what we can - and keep the insurance paid-up.

In the "H" mode mixer, a very attractive configuration for Ip3 considerations, the switches are not in parallel. I've never used a 4066 and have no experience with them. The SD5000 series, which started all this I believe, has a high conversion loss due to high Rdss. I have used those and measured variously 10-11 dB CL. It's appreciably more expensive but is a wonderful mixer, I use several in test equipment in the shop where I occasionally NEED high intercepts and G3SBI has measured third order intercepts in the mid +50's using it over volted which immediately made the following filters the culprit in obtaining anything higher.. It may be getting difficult to find, but is also available in DIP. I have had no difficulty with SSOP and have even used a few TSSOP packages in a homebrew workshop. It takes a little care, but you'd better start getting a handle on it, more and more desireable devices are only available in the smaller packages.
>

>

I have wound many transformers. Using BN43-2402 cores and even BN61 and 43-302 cores. And, I don't work for Mini Circuit Labs. But they have some kind of magic they put in the ferrites they use. I've never been able to match the performance I can get with their transformers. I have little experience with 100 KHz receivers either, but I do use their T1-6T's in a homebrew vector network analyzer that goes down to 50 KHz. For the frequency range you express interest in, you might want to try the TT4-1 rated down to 50 KHz for 200 ohm use or the T1-6T for 50 ohm use. The latter is rated all the way down to 15 KHz at the 3 dB corner. It should be obvious that you cannot measure +50 dBm third order mixer intercepts if you have transformers saturating at +30.

Try Wes Haywards lossless feedback JFET. (pp 216, IRFD) excellent reverse isolation, very low noise and can make 200 ohms if you don't like 50.

Old ARRL handbooks from the '50s and '60s will have lots of information
and schematics for the 6146. I've built several transmitters using one.
A great tube.

Older handbooks also have numerous circuits for the 807. You can
directly substitute a 6146 for the 807 in most of these circuits.

I'd guess if you need help of this sort, it would be good for you to try an HF application before you venture into VHF. Try "6146 transmitter schematic" in a Google search. You should get lots of hits. www.qsl.net/n6ev/1957.html was the first one I got, with several 6146 aps mentioned, and the subpage at http://www.qsl.net/n6ev/57-174S.jpg looks like about as simple an application as you'll find. I trust you have a license to transmit...

The valve, of course, is only part of the problem. Do you have parts for the power supply? Around 500V-600V at 150mA or so would be nice. How about a variable capacitor or two for tuning, one of which is going to have to handle over 1kV? Do you have any info on RF construction practices that you can follow?

Cheers,
Tom

A constant in rec.radio.shortwave is the quest for the perfect AM BCB
receiver. I'm sure you could kick some butt with your only competition
being the SRIII and the CCRadio.

George Heron of the NJ QRP Club demoed a cute little box last year at Dayton. It took a PSK-31 signal and converted it to Morse. He also had a little LCD display that would display a few words of the message. The little box would take a paddle input and transmit it on PSK-31.

He threatened to kit it, but I don't think he ever did. I think it was written up in either QQ or the QRP Homebrewer.

It seems to me that the source for DigiPan is available on their web site. Also, a good description of the protocol. I could be mistaken about it being the DigiPan site, but I think it was.

I realize that C is a write-only language, but you're going to find it tougher to pull the algorithm from someone else's assembler than someone else's C. Why specifically a non-C version? Seems like you're eliminating 99% of the possible sources up front.

PA3CKR mailed the Radcom reference to me. It seems that an important
figure text is not shown (or difficult to see) on internet. Radcom
September 1998 pp58, TT, fig.6: ".....The unit shall always have an
input frequency. The LO input amplitude should preferably be +10dBmas
the squarer then takes less current.
Balnce adjustment for 9MHz IF using FST3125 mixer; (1) Set the RF
signal generator to 9MHz at 0dBm. (2) Set LO to 37MHz. (3) Adjust RV1
fir minimum feed-through @9MHz. The mixer should now be correctly
balanced. Do not omit the 270ohm resistor or the squarer will become
unstable. Use ground-plane PCB."

So in a way it seems that the amateur constructor don't really need a
100Mhz oscilloscope, and still the mixer balance is more important to
achieve than what you believe is 50% duty cycle. It may even be easier
to adjust for minimum leakage than spending time with the oscilloscope
to verify the accurate pulse lengths.

I'll now have to try CD4070UBE, CD4077 or 74C86 on +10Vcc for my
experiment. Suppose the resistor values are somewhat higher. Not quite
sure why the 74AC86 circuit uses an inverter and non-inverter to
perform like an inverter, but certainly it is a good idea to use
exclusive-OR (or EX-NOR will probably do the same job) when you only
need inverters and non-inverters. Will try to modify the 4069 for
balance using the described technique.

not sure which book you refer to. tried the BFR96 with transformer and
two resistors to choose impedance, but it was a disaster. Used 22R in
series with emitter and 2k2 as feedback from tap on transformer to the
base. BFR96 draw 20mA. Wouldn't work good whether I connected 220 ohm
termination across the transformer or to the tapping. Input impedance
was closest to 200 ohm when the termination was across the transformer
on the output, but a termination across a terminal which has 400 ohm
impedance doesn't make sense to me. Tested over the range 0.5-20MHz.

So it seems that the well proven circuit for 50 ohm stage doesn't work
on 200 ohm.
Used the circuit suggested by DJ8ES, and it is very similar to those
mentioned in fig 16, 17, 18 pp188-189 in Solid state design for the
radio amateur.

Introduction to Radio Frequency Design. ISBN 0-87259-492-0. Been out in hard cover for 20 years, in soft cover for close to 10. Wonderful reference text.

The noiseless feedback design utilizes a 3 winding transformer for feedback and to set the input match. Depending on the transconductance of the Fet and the turns ratio, you can get about anything you want. Just not all at the same time. With a single turn for the source winding, (piece of RG-174 braid) the 200 ohm requirement should be even easier than getting a 50 ohm match. I usually use a number of J-310's to raise the transconductance and to increase the signal handling ability. I haven't cranked through the numbers to see what you'd wind up with for a QRP low current amplifier.

I've found a good deal on an HP counter but the specs state:

channel A: 10hz to 200mhz, 1 megohm impedance
channel B: 50mhz to 225mhz, 50 ohm impedance

I'm a neophyte on homebrew and was hoping to use this for some HF work. The 1M impedance on the counter makes me think I can't use it for HF work without an impedance match. Is this correct or am I confused?

I'm reading specs at http://www.bellelect.com/products/agilent/5384a.htm

Pete -

An interesting site on Kitbuilding by WT9W:
http://ww2.netnitco.net/users/wt9w/kit%20building.html

The PC board creation business exists today farther west of you Pete in
Dundee, FAR Circuits
http://www.farcircuits.net

What is provided with Fred's business is the PC board and sometimes a
reprint of the publication article or a set of instructions. This varies
depending upon the author or group asking for the PC boards. The parts and
enclosure is left to the builder - as well as detailed step by step
instructions (aka "HeathKit" style).

What makes a kit high-performance? Good clear instructions, illustrations,
support for beginning kit builders ?

Let's face it, HeathKit had a great business and actually set the bar quite
high for future kit companies.

If Heathkit were running today - I think Elecraft is close to what it would
look like (Manuals on-line for review, before building the kit !):
http://www.elecraft.com

A special Building Resource's Page to provide information and tutorials on
topics, such as good soldering.

Other companies offering well regarded kits: http://www.norcalqrp.com;
http://www.fix.net/jparker/wild.html ; http://www.njqrp.org ,
http://www.smallwonderlabs.com and http://www.tapr.org .

Yes, there are different kinds of packing "peanuts". A lot of the "modern" ones are water-soluble -- they typically are a gray-beige color. Of those that aren't, there are still at least a couple varieties I'm aware of...if it doesn't dissolve readily in toluene, xylene, MEK or acetone, it is almost certainly NOT polystyrene. Also, don't count on the ones that are polystyrene to be the pure, low-loss polystyrene that we'd most like to use on coils, though they're likely to be plenty good enough for most of our work. You can also use styrofoam blocks...hunks of the molded packing material, for instance. I'd avoid using the pink or greeen type...stick with white.

Like Roy, says, avoid Plexiglass -- that's acrylic: "polymethyl methacrylate" in most cases, I think. If that's right, its dissipation factor at 1MHz is around 0.014, compared with about .00007 for pure polystyrene. Polycarbonate is only a little better than the acrylic.

I've found toluene, xylene, acetone and MEK all at various of the major "home improvement center" stores like Lowe's and Home Depot. (OK, I do admit that I now have more xylene than I'm likely to use in my lifetime...)

I've found that a polyethylene bottle will hold the home-made "Q-dope" just fine, BUT the solvent slowly evaporates through the polyethylene. You might want to use a glass bottle if you have one available.

Cheers,
Tom

Are you sure that small radio is worth the effort of building up
an S meter circuit?

Would a voltmeter paralleled in the audio output give you
enough of a reading of peaks and nulls?

Paul, the 1Meg input means that the scope probe will not load a normal circuit under test,the 50ohm input was provided to do certain measurements in 50 ohm circuits,..the 50 ohm input would not be of much use in regular ham radio measurements..One thing about an older scope ,like some of the HP and Tec models is lack of affordable service parts.good luck Harold W4PQW

That input arrangement is fairly common. You'll probably find that the
1 Meg input works well with a 10:1 scope probe, which gives you a
shielded test lead and allows measurement of higher level signals
without damaging the counter's inmput circuit.

Use a dummy load as the HF termination, with a "T" adapter for
probing.

At VHF with the 50 ohm input, be sure to use an attenuator between the
rig and the counter so you don't exceed safe input voltage. Replacing
burnt-out prescaler chip gets expensive!

The "National Electrical Code" does require that all these things be
bonded to the same grounding electrode as the power service. It also
makes the driven ground rod the electrode of _last_ resort, not the
preferred method. But the discipline to do these things right often is
lacking, unless the inspector holds the installers' feet to the fire.

In too many cases, that doesn't happen. This is especially true for
lines addeded after the house is built, often with no permit or
inspection.

A four-foot toy "ground rod" completely isolated from the electric
service electrode seems to be the norm for cable TV installers in my
area. Bonding the grounds together is something I haven't seen in
either of the two houses I've owned. This puts the cable box, TV, VCR,
etc. right in the surge current path between TV cable and the power
line. When the power line takes a strike, the results are not pretty!

124. Re: 6146b lets put this bulb to work

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-05 08:48:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3CFDD056.A32403C2@eznec.com>
Source record: 43735

The 6146 and 807 are certainly not exactly equivalent tubes, and they but they are quite similar. The 807 has 30 watt dissipation vs 25 for the 6146 (35 for the 6146B), and the rated screen voltage is a little higher for the 807. But in class C service, the 807 was typically run at 750 volts, 100 mA for 75 watts input, while the 6146 could be safely pushed to 120 mA for 90 watts, and the 6146B was good for 160 mA at 750 volts in that service. 6146 heater current is a bit higher, but interelectrode capacitances and other specifications are similar. While there might be some applications where you couldn't replace an 807 with a 6146 with minor or no modifications, I think they'd be very rare. I wouldn't recommend substituting the other way, though. The 6146 was better shielded, so some circuits using a 6146 could become unstable if an 807 were substituted for one.

The tubes have different bases, so one can't be a plug-in replacement for the other. In that sense, the 6146 is obviously not a "direct" replacement.

But you can, with minor modifications at most, use a 6146 in nearly all the old Handbook circuits which used an 807.

Keep in mind, it depends on what you are doing.

If you have a circuit under test, and you want to feed the output of the circuit, presumably a circuit with a very low level output, directly into the counter, then a 50 ohm input impedance is a useful thing, presuming, of course, that the circuit was designed for 50 ohms. While the final output stage of amateur gear is typically designed for 50 ohms, there is no reason that earlier stages would be.

On the other hand, if you are poking around in a running circuit that is already terminated, you want as high an impedance on the test equipment as possible, in order not to load the circuit under test. Inputs to mixers and the like frequently have impedances of a k or two ... sticking a 50 ohm probe on one of those would seriously upset the circuit. Some sensing circuits have far higher impedances, as do the gates of FETs. Imagine putting that 50 ohm probe onto the input of a circuit with a few megs of input impedance. Virtually all the current is going to go into the counter, and the circuit won't be able to work at all.

..

Actually, I do have a MW only variation of my general coverage design. This design used a Phillips TDA1072 as the 2nd I.F. subsystem. The main thing is getting those variable caps for the preselector. Performance of this unit is similar to an AOR7030 with a Kiwa loop. I have made these side by side comparisons. Right now, I am using an Analog Devices AD9851 DDS for LO injection, but I will be experimenting with a varactor tuned VFO. Another MW/LW unit that I built used the Motorola MC13030 dual conversion receiver on a chip. Unfortunately, Motorola decided to discontinue this device. Too bad; this was a good device.

Hi,

After 10 years of sitting in a box, I just set-up my old Drake C line (R4C and T4XC). The R4C is working great. But the T4XC is giving me problems. Since it is getting impossible to find anyone in Canada to fix these old radio, perhaps someone can give me some advice.

Problem 1

When I operate the in "Separate mode", everything seems to work pretty well. But when I go to "transceive" mode (either the R4C or T4XC VFO is used for both transmitting and receiving), problems start. At first it works! But after a while, I hear a tone in the receiver. What is really weird is that when I can tap on the cabinet of the T4XC transmitter, the S meter on the R4C moves and I can hear it in the receiver while in RECEIVE mode. It seems like my old T4XC has a hidden microphone (smile). It must be some sort of weird feedback or ground loop.

If I disconnect the INJ (injection) cable the tone/ feedback disappears. Also when I go back to the separate mode, the tone / feedback disappears. Right now the only way I can operate is in "Separate" mode. I have been getting pretty good audio reports on the air.

Does anyone else experienced this? WHat might be wrong? Perhaps a blocking capacitor has gone in the Injection circuit? I doubt it is serious. But I need some help tracking the faulty part down. Any suggestions would be appreciated.

Problem 2

When I tune up on 20 meters, I initially get over 175 watts output power! But it soon drops to 100 watts. The power sometimes fluctuate rapidly at times during tune up between 100 and 175 watts. (The plate current also fluctuates between 300 and 450 mils). It can be a challenge at times to tune it. The problem is intermittent.

Any ideas? It looks like another capacitor has gone? How do I track down the faulty component?

Rob
P.S. I really wish I had a VTVM!!

When they were in regular use, the wear was taken care of by outright replacement of dial assy companents at regular overhauls. I have had one set where the cleaning was futile that required me to drift the three fixed pins of the floating mount further toward the OD of the dial, to obtain a bit more travel & tension in the worn mechanism.

That could be a bandswitch contact...or ant relay if you ever see it happen on other bands. My old Galaxy xcvr does both but is somewhat tame after a good cleaning with De-Oxit and burnishing the ant relay contacts.

I agree with Bill....It is like one of those things that goes 'bump' in the night.
I would first suspect a tube has to be reseated. Make sure all connectors are tight, and move each control on the front panel while listening to see if the sound changes. If the cause is a BAD tube, listen to the sound and tap each tube lightltly with the eraser end of a pencil....see if the sound is effected by a particular tube.
You can tap on other components with the pencil while you are at it.

I have opened up the T4XC and R4C and inspected the tubes. They all look pretty good. They are firmly pushed into their seats. But I will try your eraser trick.

The problem only occurs after I have transmitted for awhile. Then I start hearing the tone/hum in my speakers in "Transceive mode". When I tap on the T4XC cabinet, I hear the tapping in my speaker and see the S meter jump on the R4C while RECEIVING. Very strange!

Recently, I have also been getting reports of a 60 hz hum in my SSB and CW transmissions. Maybe the problem is originating in the AC4 power supply.

But keep the suggestions coming. I think it should be fairly easy to isolate the problem

138. Sweep tubes to ceramic

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-05 22:53:10 UTC
From: Skipp <skipp@pilotNOSPAMPLEASE.ucdavis.edu>
Message-ID: <adm4omoip9@woodrow.ucdavis.edu>
Source record: 43601
Cross-posted to: rec.radio.cb,rec.radio.amateur.homebrew,rec.radio.swap

In reference to another thread where someone asked questions about converting an amplifier from 6LQ6 "sweep tubes" over to 4CX250B "ceramic" tubes...

Here's a web link to a few photos of a Dentron GLA-1000B which was converted over to a pair of 4CX250's by an Italian Amateur Radio Operator. I also have pictures of the same amplifier with some of the newer Russian GU7 series tubes on board, but that's off topic. Anyway have a look if your interested.

I'm guessing but obviously something is microphonic.
Coupled with the 60Hz hum and bearing in mind the lack of use for the

last 10 years... its most unlikley.. but I have come across
microphonic capacitors and I suspect the smoothing caps prior to the
OA1 or OB2 voltage regulators supplying the HT to the VFO.
As usual, no guarentees etc etc..
I'm usually wrong ;-)

on what frequency ?. A 1Mhz timbase can 'see' the modulation envelope.

George ,to monitor transmitter up to 15 mhz,you only need to sample some of the RF output..one way is to use a coax "tee"..couple the scope probe to the center of the tee through a small HV cap,like 10 pf. at 1000 v ..adjust the scope sweep and vertical for a good waveform(like a horizontal christmas tree)I assume you are talking about AM or SSB..ARRL radio handbooks have all this, If you don`t have one you can get one at local library. good luck , Harold W4PQW

I bit the bullet and took off the front panel. What a job! I did more cleaning and the dial started working a lot better. By the time I got the panel back on, it was bad again.

I may try the beeswax idea yet. I don't really think this mechanism is worn; the radio seems to have had almost no use at all.

Someone directed me to a bama web site but I couldn't get there. Well I got there but when I tried to download the manual it wouldn't work. Maybe it's working now.

In the past, I've found beeswax at sewing stores. And yes, it's very different from paraffin wax. Beeswax is soft and kind of sticky. Paraffin is hard and waxy.

Get a puppy.
She will be so busy cleaning up after the pup that she won't even notice
your radios.

Take her on a fishing trip. Have her change the oil in the truck while
you watch the game. Lie and tell her she is sexy. She's just needs to
be 'wanted'.

>Of course the front panel has to come off, not a five minute task.
>Thank you.

While you're at it, you may want to add my ham-band bandspread
dial. It fits over the logging dial inside the logging scale.
Its still available from Mike last I looked.
Here's the blurb...

SP-600 Hamband Bandspread Dial now available

An attractive, professionally made reproduction of my old
1968 SP-600 ham band only bandspread dial is now available.
It fits on the front of the logging dial inside the logging
scale and covers 160-10M plus WARC bands.
Includes installation and alignment instructions.

I have used this with four SP-600s and had no trouble aligning
them to the dial. Not perfect but worlds better than trying to
interpolate the main dial!

Contact Mike Tobin, the old-radio-dial maker, at dials@juno.com
See his page at http://members.aol.com/rockseaent

Best, John

Hi all,
i have made an interface for TS940 + Sound Blaster that supports
A/FSK,(may be simply modified for any rig) works great, and finally
stopped all the problems dure to ground loops, keyboard look and so
on...
For wiring diagrams and info, a look at http://www.ik3qar.it on "RTTY"
section.

Hope it will be helpful.
Please add any critics, comments suggestions are appreciated!

Hey Bill,
My wife did the exact same thing and for our anniversary 2
weeks ago she bought me a new ICOM V8000 because I was searching around to
get the finals replaced in my dead TM201A..... Of course this is my SECOND
wife. The first hated the hobby big time.....

Ok actually I had that problem my self..

What ever I did was hopeless.

Until I talked to my wife seriously about my hobby... AND THEN GAVE HER THE DELIMA

a)rigs , ps ,antennas OR

b)me looking at other women(just looking nothing else)

After 2 minutes I solved my problem... Its worth a try..

So in your view, a common mode surge can occur on a single wire.

Any discussion of surge protection with that kind of
thinking is pointless.

When you are playing with your radio, you are not:

sitting in a bar, drinking away the rent money,

carousing arond with other women,

or a hundred other things that she would have a REAL reason to complain about.

I have been amazed at how many XYL's have so many problems with this hobby.

When my wife threatened to lower the boom on my HF activities due to
her dislike of ANY antenna, I reminded her of all the above points. Now
we have a deal, She doesn't complain as long as I keep the antennas
discrete. So I don't have a big vertical, but do have a nice long dipole
that I hid in the trees.

Actually she is pretty supportive otherwise, and has even bought me new
ham toys!

HI,

Thanks for thr post. Where are the OA1 / OB2 voltage regulators. I don't see them on the schematic.

Do you think it is the caps in the power supply AC4 that is the problem?

If so, what is the best way to determine whether a cap has gone bad??

181. Using narrow filters with TS940 in digital modes

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-06 20:14:10 UTC
From: Rob <Pse@NoEmail.Com>
Message-ID: <OoPL8.2663$H67.14122@tor-nn1.netcom.ca>
Source record: 43643
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

Has anyone figured out a way to use the narrow filters of the TS940 in the digital modes (using AFSK, etc). Is there a mod available?

Right now you can only use the TS940 narrow filters in CW and FSK. Not very good for PSK31, etc.

I am really impressed by the power supply of my Braun electric shaver. It
can run from 12 - 240 V AC or DC. Of course it is only 6 Watts. Does anyone
know the secret for making such a universal power supply, it isn't broken
yet so I won't open it!
Wouldn't it be nice be able to plug in your rig everywhere with no concern
for neither voltage nor polarity?

Sorry Rob, I'm not familiar with the AC4, but there has to be voltage stabilisers in there somewhere, but perhaps not OA1 OB2 etc. Duff caps are probably easiest to locate by paralleling a known good smoothing cap with the suspect smoothing caps.

Your problem is you don't have ENOUGH stuff yet. Go find a tail gate session and buy every box of junk and get as many clunker radios as possible. Don't matter if they work or not.

Now come back and pile them into your shack. Everywhere. Make a mess of it. You'll know you hit paydirt when instead of complaining to her mother "he's on that radio again" she now says "he's fooling around with those $&%^# radios again". Once it becomes plural, you have it made.

Now you can sneak in as many new radios as you want, and she'll never notice. If she does catch you sneaking in with one, you can always explain the great trade you made by swapping your old Binford 4305 with quadraflex tuning and heat seeking frequency sensors for it. Don't matter what you say, just jabber on she'll tune you out real quick once you start talking wattages and model numbers and other specs.

Works for me. I also smoke pipes. So far I've acquired four pipes, two radios, an antenna and various pices parts without her noticing.

Welcome to how a common mode surge works. Incoming on one AC power wire. Outgoing can be to earth ground on the phone line, through the network (NIC), or maybe even through the frame into a concrete floor. Go back and read those application notes from Polyphaser. Or this so simple demonstration of how common mode surge damage is avoided by enhanced grounding - Ufer ground:
http://scott-inc.com/html/ufer.htm

The destructive common mode surge enters a building on one or on many wires, passes through equipment, than exits on any other path to earth ground. There is no mystery about this 1930 technology demonstrated in those Polyphaser application notes, or here:
http://www.telebyteusa.com/primer/ch6.htm
> Conceptually, lightning protection devices are switches
> to ground. Once a threatening surge is detected, a
> lightning protection device grounds the incoming signal
> connection point of the equipment being protected. Thus,
> redirecting the threatening surge on a path-of-least
> resistance (impedance) to ground where it is absorbed.

or here:

> A properly installed lightning protection system
> intercepts the lightning bolt between cloud and
> earth and harmlessly conducts it to ground without damage.

or here:

http://lists.contesting.com/_towertalk/1997-April/004413.html
> The basic scenario is to install a Single Point Ground
> System that is installed at the building entry. It
> shunts everything to ground before it goes in the building.
> If you can keep it outside, then you don't really have to
> do much inside.

Its a fact that a common mode surge can enter on a single wire. Also, it only takes a single wire to shunt a common mode surge from the air terminal (lightning rod) to earth ground. It only takes a single wire to shunt a CATV surge or phone line(s) surge to earth ground. It only takes one wire to carry a common mode surge, destructively, into household appliances. These are basic EE concepts. Incoming on the single wire and outgoing to earth ground. Basic concept of electricity as demonstrated in primary school science calls

this a complete circuit. Where is this so difficult to
understand?

HI Mike,

Well the AC4 power supply is very simple. It produces 650 v DC, 250VDC, -45 to -65 vDC for bias and 12 VAC. (The 12VAC is used to power the tube filaments. I don't think it is ever converted to 12 VDC inside the T4XC).

The AC4 power supply converts the 120/240 VAC to the various DC voltages using seven IN4005 diodes. It has a number of resistors as voltage dividers. To smooth the DC it uses a number of capacitors two 125 MFD capacitors for the 650 volt DC line, two 100 MFD caps for the 150 VDC line and two 20 MFD caps for the -45 to -55 VDC bias line. The caps are all electrolytic caps. (There is also two .01 MFD regular caps for the 12 VAC line)

I suspect that during storage one or more of the electrolytic caps has cracked and dried out. (Isn't that a common problem with electrolytic caps?)

If I connect a good electrolytic cap in parallel, how will that help me identify the problem? Won't I still hear the 60 hz tone / hum etc?

Of course, the problem may be inside the T4XC transmitter and not the AC4 power supply. (smile)

What does "OA1" and "OB2" mean? I am not familiar with these terms.

You might find it more convenient to use a short insulated wire coming out of the tee, and wrap another insulated wire around it, forming a small-value capacitor. This method lets you adjust the amount of capacitance by adjusting the amount of wrap. Even at the legal power limit the voltage will be only a few hundred volts as long as your SWR is low.

A prudent ham will allow for the unexpected however, so 600-volt rated insulation would be a good choice for both wires.

And the ever famous "it's not mine, I'm holding it for a friend". I always
dread the "that's not the same radio you had is it?"
I don't know how I've managed to talk myself out of a jam so often.

But I look at it this way, as mentioned above....I'm not out in a bar
drinking away the rent money, or out bowling with the guys. All she has to
do is look in the basement and there I sit..happy, but not yet content.
Between the computers and the radios, I'm surprised she puts up with as much
as she does. But when she needs money for some new clothes, or wants to go
away for a weekend I alway pay. Gets me back in her good books!

Yes indeed it does. Much of the circuitry is solid state so there is
the normal compliment of rectifier/filtering inside the xmtr.
>

> Of course, the problem may be inside the T4XC transmitter and not the AC4
> power supply. (smile)

I think the tone, etc that you are hearing might be from faulty
interconnecting cables or oxidized relay contacts in the xmtr. This is
probably separate from any hum issues.
>
> What does "OA1" and "OB2" mean? I am not familiar with these terms.

0A2 and 0B2 are common regulator tubes. Not used in the T4XC.

If you don't have a manual and schematic you can download them at
http://bama.sbc.edu

Hi Bill,

Many thanks for the post! But I hate to disagree with you. But the T4XC (unlike the R4C) has more tubes than transistors. And from I can see the 250 VDC and the -55 VDC lines from the AC4 power supply are used to power the few transistors in the T4XC (resistors are used to drop the voltage). The 12VAC line appears to be only used for the filaments. I don't see anything like a rectifier circuit. (But maybe I am blind (smile))

Taking a closer look at the schematics. It appears that the -55VDC line is fed into the INJECTION jack along with a RF signal from the VFO. Since my hum disappears when I disconnect the INJECTION cable between the T4XC and R4C, I suspect that the -55 VDC line is dirty. Maybe the caps in the power supply have gone. (But I am only guessing!)

Perhaps the dirty -55VDC Bias line is also responsible for a hum in my transmitted signal. Will a dirty BIAS line cause hum in the transmitted signal?

Besides just replacing the caps in the power supply, I don't know how else to identify whether a cap has gone. I hope I can find replacement electrolytic caps - 20 MFD for the bias line (and 125 MFD and 100 MFD for the high voltage lines)

Oh yes I forgot to ask. Will a electroylic cap work for awhile then start acting up after more power is drawn from the power supply? The bias voltage is supplied when the T4XC is turned on but maybe the current increases during transmit!

That is what is happening here. The T4XC works great for the first 5 minutes of transmitting then the hum etc appears in my receiver and in my transmitted signal. It does not stop until the T4XC is turned of and later turned on after it has cooled down.

4CX250 tubes aren't the best for IMD performance -- but, they are cheap
and available.

Hi, I'm thinking of building a SW receiver..

Where are the best places to buy parts (crystals, capacitors,transistors, etc) besides Radio Shack?

Thanks,
Bruno Hach&#65533;

www.mouser.com would be a good start for caps. Not sure if they will
have what you need for the HV though. But since you're getting hum on
receive the HV wouldn't be the culprit.

Well, it can surely start to degrade after it heats up a bit. There's
no current thru a cap, but transmitting will definitely raise the temp
in the PS. Can you measure any voltage difference in the -55 line in
the hum vs no hum condition? Often a bad cap will pull down the
voltage.

Ummmm... RS would be about the bottom of my list for any serious
endeavor such as you describe.

Digi-Key and Mouser Electronics would be among my top choices.

It will do just fine. Of course its a whole lot easier just to replace the filter cap(s) in the -55 circuit. You can possibly get something usable at Radio Shack.

Hi,

Well I only hear the hum during receive when the Drake C line is in "Transceive" mode where the INJECTION signal from the T4XC is being fed into the R4C. I do not hear the hum in the "Separate" mode where the VFO on the R4C determines the receive frequency and the VFO on the T4XC determines the transmit frequency. The injection signal from the T4XC is not used in that case.

I agree. I doubt the 650 HV is the culprit. It is likely either the 250 VDC or -55 VDC lines. (More likely the -55 VDC line as mentioned in my previous post).

I will see if I can find a pair of 20 MFD electrolytic caps for the -55 line. Do you know what the rule of thumb is to determine the voltage rating. Should I be looking for caps rated at twice the voltage (i.e. 110 volts?)

Bob are you sure you have an SP-600? The tuning mechanism is geared not
rubber friction feed here!
If it's not smooth then some of the bushings have dried. A shot of WD-40
will certainly loosen them up but suggest you clean them.

I can't seem to find anyone selling 20 MFD caps. But It looks like I can easily get 22 MFD electrolytic caps rated for 160 volts from mouser and other places.

Please correect me if I am wrong but I don't think using 22MFD (vs 20 MFD) will be a big deal for use in the AC4 power supply. (I guess I could always use two 10 MFD caps in parallel. But that will be more wiring and I doubt there is much room!)

What do you think. Will 22 MFD electrolytic caps rated for 160 volts work as smoothing caps in the -55 VDC bias line?

The schematic calls for 20uf and the original parts list says 40uf so I guess its fairly non critical. A 22, 33 or even 47 should do the trick. 22 is the standard value these days in place of 20. Voltage is shown as 150vdc, so the common modern equivalent will be the 160. Note that this is a dual capacitor. Space shouldn't be an issue. A 22/160 cap is about the size of a cigarette butt. If you are going to order from Mouser, get the 140-HTRL-**** version (high temp).

Source record: 43574

Chris:

If you mean 1500 VAC coming out of the transformer, going into a doubler, you may have more DC than you want. Assuming a capacitor input filter with enough capacitance for good dynamic regulation, the DC output you will get can be about 2.828 times the RMS AC of the transformer...1500 VAC into a doubler will give over 4 KV under no-load conditions. You could use a choke input filter, with enough bleeder current to keep the no-load voltage from climbing too high, but the bleeders will consume many expensive watts.

You may be able to use a transformer more like 1000 - 1100 VAC to give something close to 3 KV.

I think I may have narrowed down my problem with my T4XC.

I took off my cover and started to gently knock on the tubes etc with my pen. The minute I hit either V9 (12AX7) or the electrolytic cap beside it (C107?), the S meter would jump to S40 over 9!

I suspect that either V9 (12AX7) or the cap is defective. I hear that tubes can be microphonic but can caps??

Does anyone know where I can get a replacement 12AX7 or a replacement for the 60 MFD 250 vdc electrolytic cap? (I don't think they make the metal electrolytic caps anymore).

Am I on the right track??

Source record: 43575

There are two basic ways to design such a power supply.

First, you can put in some sensing elements to decide the input range and switch in the appropriate components.

Second, you can design a power supply that will work from the entire range. It will have a variable duty cycle such that the output is always within certain reasonable limits.

I think you are interested in the second approach. The problem may be efficiency, and the output will be difficult to filter. A short spike of 300 Volts will have to be filtered down to say 12 Volts by virtue of its having a duty cycle of 4% or so. Hard to supply large currents under these conditions, although there is nothing to stop you from trying.

Many computer power supplies will operate from 100-240 Volts without a problem.

The thing that makes the razor supply practical is that it is low power. And doesn't care too much about ripple and other noises.

By the way, if you disassemble it you won't learn a whole lot about its design.

73, Bob

Many thanks for the reply. I did not realise that they made high temp caps!! Yes if I order a cap I will get the high temp version but I think it may not be a cap in the power supply after all.

I took off my cover and started to gently knock on the tubes etc with my pen. The minute I hit either V9 (12AX7) or the electrolytic cap beside it (C107?), the S meter would jump to S40 over 9!

I suspect that either V9 (12AX7) or the cap is defective. I hear that tubes can be microphonic but can caps??

Does anyone know where I can get a replacement 12AX7 or a replacement for the 60 MFD 250 vdc electrolytic cap? (I don't think they make the metal electrolytic caps anymore).

Am I on the right track??

I've never seen a can type cap do anything like that. I'd be more
suspect of the tube or something else in the immediate area.

One of the best places, period, is Future Electronics. They have a good supply of the Phillips radio parts, along with the Murata ceramic filters. They even have the photo sensitized PC boards, along with the UV exposure light,if you want to roll your own. I've found that if you use Ink Jet or Laser Jet transparancies, if you have a PC board layout program, you can print out your own tools. Digi-Key is a good source for ECS crystal filters, along with the other suppliers that the other folks have mentioned.

It must use some form of switched mode PS, with direct connection (no
transformer) to the supply, with a bridge rectifier. There is a transformer
on the output, of course.

Perhaps a nice, expensive, linear amplifier under the bed might help.
Those things have been known to generate a little heat. If nothing else,
it will (generate a little heat) once your wife finds out how much you
paid for it - many people warm up when they're yelling at someone else.

Same here. My wife bought my first radio years ago after she realised I wanted one and has never complained once about anything I've purchased since. In fact, I have the perfect wife - she likes fishing, boating, country music, SUVs, cooking steaks on the grill, wearing tight pants, and practical jokes. In fact, she even points out the girls with short skirts I might have missed. What more could you ask for in a woman?

but, sadly, have little financial return on your investment on resale
:-(
Any commercial equipment tends to maintain its resale value, homebrew
is usually an instant write-off of outlay, and bucks for bang,
generally (but by no means always) inferior to commercial.

Source record: 43590
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.antiques.radio+phono

I recently purchased a Hallicrafters S-38C for my brother. I understand from looking at it that the chassis carries a potential. After making some inquiries I have learned that to remove the shock hazard I need to install an isolation transformer.

While I'm still somewhat ignorant of electronics, I'm fairly handy (I recently restored an old SX-99 to working condition). But I feel that working with transformers is a bit out of my league. I would appreciate some help from someone who has done this before. Basically what I'd like to know is what kind of transformer to buy (be specific), and how/where to install it. Any help would be appreciated!

Thanks!

It also helps if you say where in Canada, because in some places
there are still local stores where you can buy parts.

An important thing to watch for is hamfests or fleamarkets put on
by local ham clubs. The Radio Amateurs of Canada keep a list of
such events at http://www.rac.ca What you will find depends on
what people are selling at any given time, but especially if you
are just starting out, they are a great source of staples, without
the higher cost of buying from Radio Shack or even other places.
Along with parts (and you probably won't find the absolute latest
parts), you can usually find data books cheap, back issues of the
amateur radio magazines, test equipment, used books related to amateur
radio and electronics in general.

You can also get a lot of parts out of abondoned electronic equipment.
See a VCR waiting for the garbage truck, and chances are the power
transformer is still good (maybe it will put out voltages that aren't
as useful as a bought transformer, but transformers can be some of
the more expensive parts to buy), plenty of ceramic capacitors to use
for bypassing circuitry, all the resistors you care to pull off the board.
A lot of transistors, useful for when you don't have a crucial
application. Other electronic equipment will likewise offer up
the staples, and depending on what it is, offer up some unique components.
Of course, the more recent it is, the less useful the parts it will
supply.

Your question in some ways depends on what you want to build. If it's
some slick design out of the latest magazine, you will probably have to
mail order, and your choices of places that carry the needed parts may be
limited. But if you are building something from a few years ago, or
something reasonably simply, chances are the parts are readily available
(even at Radio Shack though their prices will be higher).

It is best NOT to change the internal ckt in the ac/dc set. Instead use
a external isolation xfmr or use two back to back filiment xfmr's. Then
the S-38 is isolated and you can ground and use in a safe mannor.
Otherwise use a polorized plug. I grew up with ac/dc sets in the 50's
Good luck 73 Sparks W4EAS

Hi Bill,

I found a spare 12AX7 kicking around. I replaced the suspect 12ax7 with the spare. I get the same behaviour! Maybe my spare is also defective.

The T4XC uses two 12AX7. I am thking of swapping them. I just don't know if it is a good idea.

Or just maybe the tube socket is defective. Maybe I can use some sort of anti-oxidizing stuff (Oxidet?)

The weird hum etc seems to occur only after I transmit for a few minutes. After I stop transmitting for a few minutes, sometimes the hum etc disappears. Very weird. It obviously only occurs when one of the components heats up during transmit.

I am pretty sure there is something wrong with the mic amp / side tone generator circuit. Maybe the electrolytic cap beside the 12ax7is the cause. The cap is connected to the plate of the 12ax7 and to 250 VDC. It might explain why I hear the hum DURING receive (coupled through the Injection cable). But why is it microphonic?

I also notice the plate current going from 300 to 400 mils during tuneup. I think itis the same problem.

Can I still get metal can caps? Or will any 60 MFD electrolytic cap rated for 250 VDC due?

Rob

The ARRL Handbook has a circuit for this, using a mixer.

Hi

Well i experienced the same problem myself....long time
ago.
But after a while I dicovered that I was using the wrong
tactic on her.

I startet to treat her the way I treat my equippment.
Gently in the beginning; First very smooth..trying out what
band she`s on? Then I check out what mode she`s in?
If she is in the "sleepy" CW-corner....save the poppers boys!
But...if she is on the SSB-plane....I slowly pump up the
volume....Pop a Champagne etc.....watch for the background-noise (bubbles)
appearing in her lower part
of the eyeballs? Now`s the time to put the processor
into play...not too heavy in the beginning...better easy
uppwards with levels of bubbles?
Wait untill the band really opens up...then u give her all
that u`ve got,inncluding the afterburner...forget leagal
limits and go for it !!! (USB or LSB ??? it`s her choice.)

Never had a complaint since I changed my tactics??
Hi hi hi !!

es vy 73!

Its entirely possible that you have more than one problem. Having a
tube in a low-level/high gain stage like a speech amp that appears
microphonic shouldn't necessarily be considered a problem unless it is
particularly sensitive.
>
> I also notice the plate current going from 300 to 400 mils during tuneup. I
> think itis the same problem.

I'm not sure exactly what you mean. If the idling current is changing
then that might indicate the -55 v line is changing. But erratic output
power/input current could be a zillion different other things.
>
> Can I still get metal can caps? Or will any 60 MFD electrolytic cap rated
> for 250 VDC due?

Use a small 100 mf/250 volt one temporarily to see if the can is really
bad. Can caps are pretty hard to find. Anything you might run across
will probably be older than what you have now!

You've mentioned a number of different symptoms and its hard to see how
they might all be related. I'd urge you to first deal with the basics
by seeing if the 250 or -55 line are different voltages when the radio
is in the 'hum mode'.

You are on the right track. The tube could be the culprit -
or even the socket. The pins may have coroded/losened up
over the years.

For electrolytic caps: in general, the capacitance value
is not critical. You could probably go to 120 mfd with
no problem. You can series 2 equal caps to get double
the voltage rating and half the capacitance rating.

You asked in an earlier post in this thread about
determining if you had a bad electrolytic in the ps
causing the hum. Here's one way to troubleshoot
that: using your VOM on AC, connect one lead to
ground through a .1mfd 450 volt cap. The voltage
rating is not critical - just be sure that it is
higher than the supply voltage by a good margin.
And you could use a .22 mfd or a .01 mfd or anything
in between. The purpose of the cap in this test
is to block DC. What you see on the VOM on the AC
scale is the ripple voltage, and generally it should
be pretty low. If it is within a couple percent of
the DC voltage - say less than 5 volts on a 250 volt
supply - that's probably good. Start with the highest
AC scale and work your way down - that's to protect

your meter.

If I were doing it, I'd install the isolation transformer external to the radio; even though S-38's aren't exactly rare, I wouldn't want to be trying to adding something that would change it from the original. I'd look for a small (100VA? 150VA?) isolation transformer in a case with a cord you can plug into the wall, and a socket into which you can plug the radio. Sorry, I'm not going to get more specific than that...but you might have a look on, say, the MCM Electronics web site for such a beast.

However, the chassis should not be "hot" except through a couple of capacitors, one to each side of the line. The audio output is transformer-isolated, and the antenna input is link-coupled and therefore isolated. It _would_ be a good idea to be sure the caps from the AC line to the chassis are in good condition, and that nobody has done anything to compromise the isolation otherwise. Admittedly, the rules for line isolation are now rather more strict than they were in 1950 or whenever it was built, so an isolation transformer could serve as an added measure of insurance. But you should be able to _ground_ the chassis, also, to provide protection. (Expect the caps would trip a GFCI...)

Cheers,
Tom

>
> Thanks!

What you are describing is an isolation transformer. You plug
the transformer into the wall receptacle - and you plug the radio
into the receptacle on the transformer.
Specs: input 120 VAC, output 120VAC. Current - that depends
on how much current the SX99 needs. The isolation transformer
needs to supply at least as much current as the SX99 is rated
for. Bring money - it won't be a 5 dollar item.
Be sure it is an *isolation* transformer. I saw one advertised
somewhere that was an autotransformer, not an isolation
transformer. You do not want an autotransformer.

There is another way to provide the safety you want, and
it is a lot cheaper. You can install a 3 wire cord and
plug, and use the SX99 only with properly grounded
receptacles. The green ground wire in the 3 wire cable
connects to the chassis. The white wire in the cord
is also electrically connected to the chassis through
existing circuitry. You will need to have someone
who knows how tell you which wire (white and black)
connects where.

Take out an ad:

Addicted to ragchewing, thinking of dropping another $5K on equipment? I have the solution - proven results, you won't buy another thing as long as you have this. One left, hurry before she's gone. Will consider trades for existing new/used equipment or other offers.

...or you could just be blatantly honest...

Take my wife in exchange for your used amateur radio equipment. She won't let me further my hobby so if you're getting out, she'll make sure you stay that way. All trades completely final.

If nobody bites, you can always dangle a high ticket item in front of her that she really really wants and wait for her to start chomping at the bit about getting it, then spring the compromise on her. This could get nasty though when either A) she figures out what you're up to or B) she agrees and that becomes the norm for all of your future purchases.

However you proceed, please - keep us posted so those of us luck...errr..unfortunate enough to not be married yet will know how to handle ourselves should we ever get into the same situation.

Thanks for the tip for checking out electrolytic caps. I will see if a I have a 400 volt Cap for to hook up top my meter.

I think I should be able to track it down since I can easily get the T4XC into "hum" mode.

But for some people, they have to PAY to have someone take her.

Why buy her a diamond? She won't last forever!

If there's an outdoor market or farmer's market in your town try that.
I almost always see someone selling beeswax at Portland Saturday Market
(and when I lived in Seattle, Pike Place Market).

Motorola (ON Semi) has a line of off-line switcher chips which work something like this -- the AC or DC input is rectified and filtered, fed into a MOSFET, the gate of which is controlled (chopped via pulse width modulation) by one of their chips, and the resulting square wave fed into a transformer. The trick is to get the duty cycle of the pulse width modulation low enough so that you get something approximating the required voltage on the other end of the transformer. The feedback loop to the switcher chip is isolated from the line -- either optically or via a separate winding on the transformer. I have a battery charger for one of my cameras which will run on anything from 6VDC to 230 VAC.

One little piece of information.

You may encounter some three-conductor
power cords
with the following colored conductors: Brown, Blue, Green/Yellow

This is the new color coding that was adopted a couple of years ago by ISO
or some international standards body like that. Europe has used it for
years and some imported power cords are actually coded like this. The
USA hasn't quite adopted it yet, so it's not likely you'll find it in a
hardware store (yet).

Anyway here's the break down:

Live (Hot): Black or Brown (goes to the narrow pin on a polarized plug)

Netrual: White or Blue (goes to the wide pin on a polarized plug)

Ground (Earth): Green or Green/Yellow

Greetings,

Give her lots of help, especially when she works in
the kitchen. Try to get each item just before she
needs it. Pick up anything she sets down and clean
it and put it away. After a while, she will ask you
to do something else. Then you can go to the radios,
but break off if she asks you to do anything and help
her. You do not want her to think of the radios as
her competition. Check with her before you buy anything.
Ask her lots of questions about what you should do.
Get her to think of the purchase as one of her buying
decisions. Agonize over every choice and share
the experience until she asks you to just buy it
and leave her alone.

Also:
- Fix things for her so she has a reason to
keep you around.
- Remember you have the last words, "Yes dear."
(If you do not believe me, ask anyone happily
married for 50 years.)
- Also, she is always the best. No one cooks
better, looks better, drives better, etc. .
Let others provide the reality checks. You
just provide the always ready support.
- Use humor (not same as ridicule).
- Acknowledge the fact, "You are wrong and
she is right."
- Listen to her but do not try to suggest
solutions to her problems. She wants
acknowledgment she has had an experience.
Read "Men from Mars, Women from Venus."
- Acknowledge and praise every thing she
does for you.
- She puts her life at risk to have your
babies. When someone puts their life at
risk for you, you need to take care of them.

Sincerely,
Bill Thomas

Or something worth selling later as another poster mentioned?

I built a 'nice' receiver in the 70s. Put about $200 in it (in 1970s dollars) and it wasn't too bad a performer. I admittedly got more out of the learning experience.
It was full of nice xtals, filters, 40673s, CA3028As so its probably worth something now.

I wouldn't do that! Those capacitors can carry quite a bit of current. My first receiver was an S-38D, which I once grounded. When I turned on the power, an arc formed at the power switch, and it continued until I raced downstairs and frantically threw all the house's circuit breakers. (The arc was between me and the plug.) This made a big impression on my parents, who never forgot it. I didn't either. And I'm sure you won't, either, if it happens to you.

Use that isolation transformer!

AC/DC's are no problem. I don't understand why you would bother. Granted, it was a cheap way to do things back then. They are not, however, particularly unsafe with normal precautions. The S-38 was not a serious communications receiver anyway (more geared to SWL'ing). Used for causual listening - I would think it would be fine the way it is. As someone else stated - many of us grew up with AC/DC sets and they hardly ever caused any problems.

I fixed it! I added a spring to increase idler pressure and now it works perfectly. What a great radio! And it's beautiful, if you like well made and nicely designed machinery.

Now, unfortunately, I will have to sell it. It's a beauty, pretty close to mint condition, and everything on it works as it should. Covers from 550 kHz to 54 MHz, six positions of selectivity, S meter and audio meter, has accessory crystals for all WWV frequencies (including some they don't transmit on any more), and a lovely cabinet.

Calibration is just about dead on. It's stable too.

Does anyone have an idea of its value? It's a half century old, and represents a style that no longer is manufactured, from a company that, I believe, is long gone.

The S-38 I had, I forget which model, had the chassis isolated from the
metal cabinet via rubber mountings. So it wasn't an automatic killer
<G>.
If the rig in question also has them, restoring those mounts should be
the first order of business.

Well those who never built anything (and I don't mean a kit) will never know the satisfaction that comes from seeing something you designed actually work.
The value in doing this is priceless regardless how good the design is. Homebrew is about learning. It doesn't have to be complex and can be something as simple as a keyer or oscillator. Nearly Anyone who has the desire can build something regardless of their ability. It's good for your mind.

Thanks for those links! I see the two completed sales were at $405 and $785. If there is one on ebay at $355 with bidding in process, I guess mine should be worth something in the vicinity of $400. (I think the $785 figure is too high, but what do I know.)

Mine includes a very nice case.

Hi All

I'm looking for a schematic for an old 27MHz CB, PLL02A AM only chassis. The actual unit is Ray Jefferson CB-845, but I know this chassis was very common amongst various makes/models (Pearce Simpson, etc). I used to have the schematics but they got lost somewhere in moving house, so if anyone would have a copy they could scan or photocopy, it'd be much appreciated.

Also looking for any info on an FM receive board to build to add to above radio for conversion to 10m FM. FM Tx is easy, but the only design for FM Rx board I have is very, very old so I'm looking for any recent designs. Again, any info very much appreciated.

Oh, you have that right. How I rounded her up, and why she continues
to put up with me, is far beyond my comprehension. I guess love is a
powerful thing - it screws up a person's mind, and their common sense.

I wouldn't put any weight at all on an ebay price while bidding is in process. It's not at all uncommon for prices to change a huge amount in the last minute of bidding. Ebay offers automated bid raising, and there are vendors that offer products to refine the automated bidding process. So a huge number of bids can be, and often are, given in the final seconds. It's not like the auction down at the arena. The final prices are the only thing you should go by.

You can use a JFET to buffer the AGC voltage from the detector diode to drive an S-Meter. If you need gain, use a common source; if you have enough driving voltage, use a source follower.

No, a much better approach to that is to say you're buying radio equipment so the two of you can talk as she is riding around town in the car. This works especially well if the two of you don't communicate much around the house in the first place - some talk deprived wives will do almost anything to talk more (especially if she watches talk shows aimed at women - these shows insist "communications" is the holy grail of marriage).

If she isn't fully convinced, explain how a $1500 base radio, a $500 mobile, and several thousand dollars worth of accessories (power supplies, meters, antennas, and so forth), is much cheaper than a cellular phone when you include the monthly charges for the cellular. Okay, perhaps you shouldn't mention the prices unless she is really dumb.

By the way, don't worry about actually having to talk once you get the equipment. If you purchase a radio with enough knobs and buttons, she will never figure out how to use it. Especially if you're a little vague when explaining it to her, and you slightly change the instructions each time (insist she must turn the frequency knob this direction the first time you explain it and the other direction the next time).

Don't forget to scare her a little as you explain how to use the radio. For example, "never touch this (something almost impossible not to touch) when you're using the radio or you'll break it." Mention how expensive the radio is and how much it will cost to repair if she breaks it.

If you're good at all this, she will never figure out how to use the radio, and will too afraid to try. At that point, you can blame the lack of ability to talk on her and she will actually believe it.

After about a month, explain (as sincerely as you can) how much of a mistake it was to get a radio for her car ("it's just too complicated for you to use in a car"). Offer to get her a cellular phone instead - much easier to use. You can then move her radio into your vehicle and have a nice mobile to use.

One last thing, if you really do get a cellular phone for her, don't forget to take the phone off the hook at home whenever she is driving around - you'll be far too busy talking on the radio to actually talk to her. :-)

Your technique is good, just not fine tuned quite yet.
Try this, it's low risk:

Bring a rig from your car through the kitchen. When she asks, tell
her you are going to fix it for a guy at work. After it is "fixed"
take it back right through the kitchen, make sure she sees it. Make
sure she sees equipment LEAVING the house, this is crucial, it's the
patented part of my procedure. Keep this up, doesn't matter what the
crap is (old test equipment, HTs, old power supplies, new transceivers
in nice clean boxes). When she is trained well you will know it, she
won't even look up, or else she will say, "Please get those Yaesu
boxes into the basement and out of my kitchen.!"
"Yes, Dear"

>> AC/DC's are no problem. I don't understand why you would bother.

When I was a kid in the 50's, we had a 78 rpm record player with a
metal arm on it. We'd use it on the back porch which had a concrete
floor, and we kids were always barefoot.
Sometimes we would grab that arm and get the s___ shocked out of us.
We figured out (we didn't know why) but if you put the plug in the
wall the other way it wouldn't shock us.
Geniuses we were.

To sweeten the pot, you could put the ad in the "business opportunities" section - a woman like that would probably be thrilled to help other wives with their husbands' radio addictions. When the wife gets tired of screaming at the husband, the "hired gun" could continue nagging for her. Of course, doing this probably won't make you too popular with the other radio operators in town, but at least she'll be out of your hair if someone takes you up on the deal - that is until your new wife hires her down the road. :-)

More than any other [basically nonproductive] hobby I have ever
pursued, my wife just doesn't get ham radio and thinks it is
ridiculous. Every time the UPS man dropped off another box, I took
grief. Yet she likes and participates in off-roading, fishing,
camping, kayaking, etc.

I had to buy peace by agreeing to $3,000 more in new car frills.

I found Deoxit! But on their website, Dexoit comes in many flavours. (see
below). What is the best for cleaning tube sockets? POTS?

Part No. D5S-6, DeoxIT D5, 5 oz. spray
Part No. D5MS-15, DeoxIT D5, 15 gr. minispray
Part No. DP5S-6, DeoxIT DP5, 150 ml. pump spray
Part No. D100S-2, DeoxIT D100, 2 oz. spray
Part No. K-D100P, DeoxIT Pen
Part No. K-D50W, DeoxIT Wipes, 50 count
Part No. D5L-32, DeoxIT D5, 944 ml. container

How so you use Deoxit? Do you just spray into the holes, wipe off the
excess and reinsert the tube?

I typically use the D5-5 oz spray. (Thats about all I can afford) For
tubes/sockets I just spray the tube pins then insert the tube in the
socket while wet and wiggle it around a bit. Let it sit for a while so
that whatever deoxidizing it does has a chance to take effect.
After about 15 minutes wipe up any excess. You can use this also on the
phono jacks of your interconnecting cables, bandswitch, noisy pots, etc.
DON'T use any sprays on the radio while its powered up!

-Bill

How you add FM might depend on the conversion scheme of the receiver.

Assuming it uses a 10.7MHz first IF, dig the FM IF strip out of
some consumer equipment. 49MHz Superhet walkie talkies (they are
license free at least in North America), often but not always are
double conversion. A lot of 49MHz cordless phones are likewise (and
between the base and handheld, offer up two FM IF strips).
Scanners would too, and of course a lot of two-way equipment.
Find the right piece of equipment, and you'll get a wideband filter
at 10.7MHz (often a ceramic filter from FM BCB use), an IC that will
do the conversion to 455KHz and provide the full FM IF strip, a crystal
to do the conversion to 455KHz, a 455KHz narrow deviation ceramic
filter, and the coil for the FM detector. You may also find something
along these lines in older cellphones, but I'm not sure how often they
used a 10.7MHz IF.

Depending on what the equipment, you'd either leave the circuit board
intact, and feed the IF signal from the CB set. Or maybe cut away
the unneeded circuitry. In some cases, it might just be easier to
extract the components, and build it up on a new circuit board.

You may only need the 455KHz area, if the CB set uses that for
it's IF, and you can find a spot where the bandwidth is enough
for FM (maybe not much of a problem, because I gather a lot of
those double conversion CB sets likewise used a broadcast FM
deviation ceramic filter at 10.7MHz.

The neat thing about the above is that you will get all the
components in one place; I find these things at garage sales

quite a bit, for under ten dollars (well, not the scanners).

Just about any old limiter/fm detector IC will work at 455KHz,
so you really have plenty of options, so long as the IF bandwidth
is wide enough.

That was clever wasnt it, the "read a book" remark!....

You have a few options.

Obviously you could use an end fed wire, with a decent earth and good ATU.

There are so many good auto ATUs out there that you could just hang your 90 feet of copper, as much in the clear as possible and get the auto ATU to do all the hard work. Simple, OK results and the ATU does all the hard work! ....but not very Homebrew :)

I am a BIG fan of the W3EDP type antenna. The antenna element is 84 feet long, ideal for you. It covers 3.5 to 30Mhz, and requires some short counterpoises instead of a proper earth. Have a look at this example... http://www.g3ycc.karoo.net/w3edp.htm

As for how you would use it on 160M, Im sure its possible, with a longer counterpoise, and switch in a second cap! But as for 6M, I'd recommend a second antenna, maybe a simple dipole, or for some extra gain, perhaps a double extended zepp(should hide nicely in the loft if low profile is a concern)

Trapped dipoles are also an option, but if more than 3 bands are attempted, the system becomes very lossy. ...for 160 - 6M, I would even attempt it.

You might try a "fan dipole" which is basically multiple dipoles fed
from a single coax. I made one that was a half size, half wave dipole
for 160M with loading coils at the halfway points so that it was about
120 feet long or so, then a dipole for 75M and 15M. This avoids traps
and will give you normal sized dipoles (in your case, <= 90 feet)) on
40M through 6M. They all interact, so you need to prune each dipole, but
once you have them tuned, it's done and ready to work.

Does anyone know of software for designing hairpin filters on printed
circuit boards that
is within the reach of home hobbyist?
I know there are some expensive software packages available but I can't
afford it and was looking
for something more reasonable that the homebrewer could use to design
filters in the 500MHz to
5GHz range.
Thanks!
Mark

Have you considered a computer uninterruptible power supply? There are usually a lot of them on ebay as IT departments upgrade their equipment. Battery condition wouldn't be an issue as isolation is your only need.

Another source of transformers is automotive battery chargers and Malibu light power supplies. I see a lot of these at garage sales. Hooking two reasonably matched transformers back to back as previously mentioned would get you an inexpensive isolation solution for your bench.

I once converted an S-38E (bought without tubes) using the power transformer from a junk audio generator. I used a silicon diode to replace the rectifier tube and rewired the other sockets for 6 volt filament tubes. It worked fine. Just make sure the 6.3 volt winding will power the remaining 4 tubes.

Regards,

Ron Banks

Bruno,

Digikey <http://www.digikey.ca/> and Newark
<http://search.newark.com/canada/welcome.phtml> have Canadian pricing
for their online ordering. Otherwise just about any US electronic
component retailer will ship to Canada; Mouser, Jameco, etc. See
Google's Directory or dmoz.org.

If you are looking for a kit, you might consider kits from Ten-Tec
<http://www.tentec.com/rcvrkit.htm>, or Ramsey Electronics
<http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=SR2>,
Vectronics
<http://www.vectronics.com/vectronics/products.php?prodid=VEC-102K>, MFJ
Enterprices
<http://www.mfjenterprises.com/products.php?prodid=MFJ-8100K>

or some cheaper ones from
<http://www.sciplus.com/category.cfm?subsection=2> or
<http://www.elexp.com/kit_2srk.htm>.

Another idea is the ZN414Z or its replacement the MK484. I'm not aware
of a North American supplier of the ZN414Z / MK484. The MK484 is
available from Maplin.co.uk at 42 pence (about 1 dollar Canadian). You
can make a very simple Tuned RF receiver with a MK484. See
<http://www.mitedu.freeserve.co.uk/Circuits/RF/ZN414SW.htm> and
<http://w1.859.telia.com/~u85920178/rx/zn414.htm>.

Maybe a dipole isn't your best bet. If you can string up a loop
antenna with about 270' feet total wire in the loop, you'll
have an antenna that will cover 80 - 6 with proper feed and
your tuner. I feed mine with ladder line to a fat 4:1 current
balun with a short piece of coax from the balun to the rig.
For 160, I short the coax at the PL 259, and feed the thing as a
random wire. I ran some 120' runs of wire on top of the ground and
tied them to ground at station ground. On 160 and 80, this is a
skywarmer antenna with effective coverage of about 300 miles.
On higher frequencies it acts more like a dipole. It stinks on 6
meters - but you _can_ load it and use it there. But on 6,
you can install a dedicated dipole in addition to the loop.

The VIA plots the SWR response of an antenna over Freq on the built in LCD. The computer hook up is "After the Fact" for documenting the response. It also measures complex impedance including sign. Probably could be built with $45 worth of parts, and the kit sold for ~$125 to $150. If properly designed, accurate, stable, Calculator sized, and didn't eat batteries, it would put the MFJ 259B/269, Autek RF-1 and AEA Via out of business. If you need someone to design the digital part (PIC programmer Expert here) I'll volunteer! I'm not much good with RF design or complex impedance stuff, but from the A/D converter back, I'm darned good.

This sounds like a very cool idea. Something along these lines has been on my homebrew to-do list for a while now, but it's behind a few other projects. I, too, could contribute to the PIC part.

Another thought.....

One of the things on my to-do list has been a purpose-built rig for traffic. Traffic nets have a pretty structured way of operating. Generally, NCS is on some theoretically fixed frequency, but never quite right. Stations are expected to zero beat him, so the net frequency needs some adjustment, but never more than about 1 KHz. Traffic is passed off the net frequency, up or down some integral multiple of some standard spacing, usually 3 KHz.

I had been thinking of a rig with buttons or perhaps a low resolution shaft encoder for + and - 3, 6, and 9 khz. It also occurred to me that an automatic zero beat of NCS wouldn't be all that tough. It also hit me that a LED for each of those frequencies to indicate it was busy would be useful and maybe not too tough.

Since nets tend to operate on 80, and 80 isn't all that QRP friendly, something on the order of 25-50 watts would seem to be about right. Balancing that, the need to operate under adverse conditions would dictate low current draw (thus the need for something other than my 20 amp rice box).

This would be mostly interesting to ARES/RACES types, tho, so I don't know how big the market would be.

..

When in doubt, go with a Loop.. Open Wire + tuner. You'll end up with a wierd pattern on the higher frequencies, and "Cloud Warmer" on the lower freq's, but... I'm convinced the loop configuration beats a tunered (?) multi-band dipole in every regard. At 2 Wavelengths and more it's hard to beat as a "One for All" antenna. On 10 and 6 you might do better with a second antenna. My 568' loop at 30 Feet kicks arse from 80 through 15 on CW portion of the band.. I've never tried it on 10 or 6. You're mileage may vary..

I had exactly the same problem with an S-53.
After checking around with some people with experience I removed the 2
wire power cord and the two capacitors from line to chasis.
I then installed a three wire cord and connected the ground wire (green)
to the chasis. I did not install any capacitors from line to ground.

Works like a charm! And it is safe!

This fix works just fine and involves an absolute minimum of work and
cost. However, for the purists, it does involve modifying the radio;
even though it is a minor mod and easily reversed if you prefer to live
dangerously.

Still wonder about the guy I bought it from since he had it sitting on a
metal radiator (one of those old hot water things which I assume would
be grounded). Maybe that's why I got such a good price.

Good luck

check this url for a complete kit for $90.00...
I saw it at Hamcom in Dallas yesterday and was impressed..
it is well designed and comes with all parts, boards, and instructins and
the guy doing it is very good, friendly and helpful..
I think I'll get one later this year for a winter build.
It's the best valuye I've ever seen..
And you can upgrade later to a digtial readout or now, superstable etc.
good luck..

Stagger tuning will help spread out the bandwidth, when you have
multiple if stages. You tune one towards the bottom edge, the next to
the center frequency, and a third near the top edge. If you have more
stages, you adjust the pattern to give you a wider, flat response. A
sweep generator, or a tunable generator with a fairly flat output and a
diode detector after the last stage can be used to align it. (Unless
you're blessed with a network analyzer on your bench!)

First a good schematic for your specific model helps (their were 5? versions
of the S-38 model)

S-38 Schematic

http://www.nostalgiaair.org/Riders/showinfo.asp?PATH=HAL&IMG=_HAL_15-59.gif&
INF=S38

This was discussed at some length in December 2001 on the boatanchors forum

[earlier post]

Some useful links for further research (and ideas):

http://antiqueradio.org/halli08.htm

Here is an excellent web site for S-38 restoration notes. He even
demonstrates how he "recast" the knobs and notes that the rubber isolators
are absolutely necessary for a SAFE chassis (AC/DC) with the S-38.

http://antiqueradio.org/smeter.htm

The Hallicrafters Collectors' Web Site:
http://www.w9wze.org/

Here were my notes on the internal isolation "torroid transformer"
discussion for the S-38:

The UK audio designers gave me an idea to look at a toroidal transformer, as
a possible isolation transformer under the S-38 chassis, instead of the
traditional external isolation transformer Stancor P6410 (50 VA rating).

I received and e-mail for Brian Gladstone, Director of Engineering at
Plitron Corporation in Canada
http://www.plitron.com

BTW S-38 draws 30 watts at 110 Volt according to specs

Plitron makes Toroidal transformers, and by my measurements one of their 50 VA units will slip right in under the S-38 chassis. You can mount it with one screw (use the hole for the old multi-section electrolytic).
You can select from a couple of secondary voltage (110, 117 vac) models.

Presto, same $ 35.00 USD price (thanks to CDN / USD exchange rates) as a separate Stancor P6410 (50 VA rating), without hauling around an external unit.

The AC power cord (on this particular unit under discussion) must be changed to a polarized plug &
fused as well as the rubber isolation mounts repaired/replaced. Then you will again have a SAFE chassis around children. A power switch, if desired, could be mounted on the back chassis (or rework the receive/standby switch on front panel).

I e-mailed to Bob Eslinger, KR1U and he would be interested in hearing from S-38 restorers who are using this approach Torroid transformers, due to their low profile, might be a solution for some of his antique radio restoration clients wishing to maintain appearance, without the external isolation transformer.

I have three forms; the D100S-2, the D5S-6 and D100L-25C. For tube sockets I recommend the full-strength stuff, and rather than use the spray can I'd use the long capillary-tube gizmo that comes with the 25 ml container. Basically: get it all over the pin and the socket contact, then work the tube in and out of the socket, wiggle it, etc. Whatever makes the pin rub against the contact surface of the socket contact is what will clean the socket.

The D100L-25C is full-strength in a tiny bottle. It only seems expensive. I bought my first bottle in 1995, have used it on just about every contact I could get it on, and I still have about 1/4 bottle left. Their site has gone Javascript so I can't see if it's still offered on their site, but some electronics distributor around you should have some left if they don't.

Use the 100% stuff for tube sockets. The 5% stuff is okay for pots and switches and uses where you need to spray a lot of the stuff onto the contacts, but when there's only a small amount of surface that needs it, the 100% stuff works better and isn't wasteful.

Of all places, Radio Shack has at least some forms of DeOxit in their catalog. Not available in the stores, but they can order it for you.

I've built and used the TenTec 1551 Speech Processor Kit.
http://www.tentec.com/amaccyKit.htm#1551store
Worked quite well on an old Atlas 210X. It's a small board so you
could probably install it inside most boatanchors.

If you want an RF speech processor, you may be able to find one of the
Daiwa's that were supposed to be quite good, RF-440, RF-660.

It might be a god idea to start out with an old FM broadcast receiver with traditional IF transformers. The coupling the resonant LC sections determines the frequency response. In ordinary receivers the distance between the coils within the can determined the coupling and it was selected to give the required bandwidth. However, increasing the coupling between these sections will broaden the frequency response in the passband, without destroying the skirts of the frequency response. With a very firm connection between the LC sections, two peaks will appear in the frequency response with a small dip between them.

The resonators can be connected with a capacitor between the "hot" side of each coil, or by connecting the cold sides of the coils together and ground that point through a common coil or capacitor.

For instance "Solid State Design for radio amateurs" by Wes Hayward and Dough DeMaw contains some preselector examples and in the appendix some formulas and examples of various bandpass filters.

>lightning has a better path around the repeater than through
>it.

Oh, lightning. Well, no one had mentioned lightning.
I thought we were talking about ordinary surges and spikes.
No matter, the issues remain the same.

When lightning strikes a tower, it already has a path to Earth,
through the tower, albeit the path may be high impedance.
When lightning strikes an aircraft, there is no direct connection
to Earth, and indeed the lightning may neither originate nor
terminate at the Earth. It may be cloud to cloud lightning.

Regardless of any ultimate sources or destinations, we don't want
the current to pass through the equipment on the way to wherever
it may be going. So we still have a situation where we want to shunt
the conductors leading to the protected equipment so that no large
potential difference can exist *between* those conductors, and hence
can't drive destructive currents through the equipment.

(The repeater itself is assumed to be in a metal box attached
to the tower, which forms a Faraday cage for its chassis. The
whole cage may elevate hundreds of thousands of volts with
respect to distant Earth, but we don't have to care about that.)

Earth may be 1,000 feet down the tower (or in the case of an
aircraft, many thousands of feet of air to Earth). Since lightning
is a relatively fast risetime pulse, it behaves as RF, so a long
path to Earth is not at all guaranteed to be low impedance.
Thus the notion of shunting to Earth doesn't necessarily have
any relevence to our immediate problem.

But we *can* make a low impedance across the equipment
we're trying to protect by placing a MOV or gas tube across
any and all connections to the equipment.

This is essentially Earth independent. We don't have
to care if the entire piece of equipment is elevated

hundreds of thousands of volts with respect to Earth
during a strike event. We only have to care that there
are not excess potential differences expressed
across the equipment where it can drive harmful
currents *through* the equipment.

The notion that suppressors won't work unless directly
connected to Earth is simply wrong. There's no such
thing as absolute potential, all potentials are relative,
and the only ones we have to care about are the
immediate ones which appear *across* equipment
we're trying to protect, and can drive destructive currents
through the equipment. As long as we stop that difference
from being large, we're golden.

In fact, if we can avoid a direct connection to Earth, we
minimize the possibility that heavy strike currents will
even flow near our equipment. That's because ground
strike lightning is going to take every available path to
Earth, and we'd ideally like for our equipment not to be
one of them.

Gary

And where does one get beeswax? Would something else work as well?

Buy a toliet seal at Home Depot - it will provide a large supply. It is also useful when applied to the tip of a screwdriver to hold a screw to the driver in those impossible to reach starting situations.

328. Heathkit sb 104 problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-10 17:44:56 UTC
From: George <gschwab@florida-knife.com>
Message-ID: <sA5N8.6997$gs4.4168@nwrddc02.gnilink.net>
Source record: 43491

I have and SB 104 that is working well...other than one small problem I
can't find reference to in the books. It is transmitting 400 Hz BELOW the
receive freq.
Receive seems ok as WWV is exactly at 15 Mhz. and I've made a few qso's by
manually tunig UP 400 to transmit and get good reports. Appears to be off
the same amount on all bands. Any suggestions before I go through a bunch of
stuff I really don't need to?
Thanks
George, AE4MH

Hi,

I have some 6U5 magic eye valves in stock. They are unused and in
original boxes. The label is Haltron, but I am pretty sure that they
are rebranded US manufacture. These can replace EM 34/35 if you just
change the socket and alter the resistors a bit.
The price is NOK 186.70 each - about US$ 23.65
Shipping to anywhere in the world!

Best regards,

Arnold Goksyr

DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://www.demostenes.no

Thousands of different valves in stock as well as
sockets,transformers,books,caps,resistors and
other components. Web site is updated every week.
You can order on-line.

Wow, that sounds like a product liability issue for Hallicrafters.
Guess that wasn't such a big issue back when we were growing up.
Perhaps it's a good thing you DID have the chassis grounded, so it
wasn't YOU that ended up completing the circuit back to earth. I'm
truly thankful for the contributions you've made to the ham community
since then, Roy. :-)

Fortunately, I never had such a problem with mine like that. Of
course, an isolation transformer won't necessarily protect against
such arcs, and it's also a good idea to have an appropriately rated
fuse (an amp or so?) in the circuit. So, for the OP...get an
isolation transformer that also has a fuse. The schematic I looked at
didn't show a fuse in the radio. I wonder what one of our product
safety engineers would say if he looked at an S-38 or similar radio
today!

Cheers,
Tom

This person had some pretty good ideas, but switching from 1N914s to PIN diodes in the mixer stage is not the way to go. A good choice for improved performance would be hot-carrier diodes, such as HP 1N5711s. PIN diodes are good for RF switching; they yield good IMD performance.
There were some pretty interesting approaches though. Definitely a website worth bookmarking!

Hi all

I have quite an extensive search on the net but didnt find alot of
good results.
Could you guys please let me know of some simple AM radio circuits
just for a bit of listening normal broadcast radio nothing special.
I'd also like some comments about your experiences with these simple
type of circuits compared to the very elaborate ircuits. preferably I
would like to listen with ehadphones or connect to an amp as I dont
have a crystal earpiece at hand.
thanks
JD Bothma

Have you tried Sonnet Lite? I think it _may_ be able to do what you
want, but I'm not at all sure. Price is right!
http://www.sonnetusa.com/products/lite/why.asp

I was recently searching for some reasonably-priced filter design
software for some 10-100MHz stuff I'm doing, and found a number of
things from freeware to rather expensive, and I recall seeing
something in that search that looked good for microstrip filter
design for hobby applications, but I can't remember what it was
exactly now. Have you tried some web searches? Try things like
"filter design software" and "microstrip filter software" in Google,
and you'll get lots of hits. Some offer free limited-time eval
versions, some are inexpensive, some are free.
Cheers,
Tom

There is "current" through a cap -- during transmit the AC ripple
will increase, increasing the current flow in and out of the cap
as the cycle varies.

Lighting strikes to aircraft were clearly beyond the scope
of this discussion. However even aircraft have their versions
of earth ground.
http://lightning.pwr.eng.osaka-u.ac.jp/lrg/temp/plane.html
Incoming from the cloud on the nose. Outgoing to earth on the
tail. Even the aircraft had an earth ground during the
strike. Cloud to Ground lightning seeks earth ground - which
is fundamental to surge protection.

We have an aircraft isolated from earth by a best insulator
- air - and still the aircraft ends up with a connection to
earth ground.

Even aircraft are designed so that "a non-destructive path
to earth is
established." However the design is more complex for
aircraft. Earth ground point can vary with each strike - and
still damage must not result. Today, earth ground via the
tail. Tomorrow, the left wing. Same principals apply.
Divert the surge into a safe, non-destructive path.

We don't try to stop, block, or absorb lightning. Always
provide lightning - the most common and typical surge - with a
non-destructive path to that ground. This even applies to a
scenario completely irrelevant to the topic - the airplane.

Gary Coffman wrote:
> ...

347. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-11 01:51:29 UTC
From: w_tom <w_tom1@usa.net>
Message-ID: <3D0557A1.D6E81522@usa.net>
Source record: 43410

There is no earth independence when discussing common mode surges. That lightning strike will obtain earth ground through the repeater IF there is no alternative path (shunt) around that repeater. IOW the tower itself may be the better path to earth around the repeater. If an MOV is placed across connections to the repeater, then the MOV provides a surge with a path around the repeater to earth ground. Of course, making that path to earth ground is not perfect. Therefore the surge may also attempt other paths to earth through other repeater connections. So we also install additional MOVs between connectors to make repeater inputs/ outputs equipotential.

Apparently that was not understood in the previous post. To reword it: A dual purposes for those MOVs. 1) To shunt a surge to earth because not all inputs will be perfectly equipotential. 2) To shunt the surge equipotential on all inputs because the connection to earth ground is not perfect. We do both - two different operations using the same MOVs - because neither method works good enough.

Of course, to be anal, we can go into greater and more complex analysis. However, the basic concept of Surge Protection 101 remains - shunt a surge to earth via non-destructive paths.

What is this magical absorption nature of earth? Destructive surges seek earth ground because, again to make it simple, the cloud is one side of the battery and earth some miles away is the other side of the battery. The battery must be discharged. The resulting surge goes from cloud, through tower, into earth, then through earth to where those other opposite charges are located. A surge electrical circuit defined. Principal of a CG lightning strike, also well demonstrated in many publications including, if I remember, a figure in Feynman's 3 volume set called 'Lectures in Physics'.

The destructive surge does not damage electronics if shunted, by safe paths, into earth. That is the concept of both surge protection and of air terminals (Franklin rods). They both do same - shunt the surge in a non-destructive path to earth ground.

Even TV and FM radio equipment atop the Empire State Building is not earth independent. This equipment suffers about 25 direct strikes every year without damage because,

again, the surge is shunted so that it does not obtain earth ground through transmitter equipment. Even 80+ stories up, lightning is shunted (diverted) to earth ground so as to not damage expensive broadcasting equipment.

Blocking a connection to earth ground is another technique to enhance protection. Some have described inductors in control lines to protect the controller equipment. The inductors alone are not effective surge protection. They only work if the surge is provided an alternative path to earth. Those inductors are only another part of the 'system'. Without that shunt path, a critical 'system' component, the inductors would easily be overwhelmed and ineffective.

Lightning cannot be stopped. It can be diverted. Nothing can be isolated from ground. Lightning came miles through air - a perfectly good insulator - to obtain earth ground. How is anything in the tower - or even that 747 in the other post - suppose to be isolated from earth ground? Cannot happen. Although something can be more isolated, nothing can be sufficiently isolated to avoid surge damage. Isolation is effective when in conjunction with some other shunt to earth. But again we return to the same point. Diverting the surge to its objective - earth ground.

348. FS: Drake L7 RF deck parts

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-11 02:10:07 UTC
From: k9sqg@aol.com
Message-ID: <20020610221007.16120.00000613@mb-bd.aol.com>
Source record: 43411

Obtained an RF deck for the Drake L7. I'm going to remove the grid meter and possibly the on/off switch. The internals seem to be there with the exception of the tubes and one parasitic suppressor I believe. Doesn't seem like any mods and the insides seem to be complete and unmodified. The front panel is in bad shape but could be restored with a set of plastic inserts. The end caps are missing. At any rate, a lot of parts will remain and are for sale. In fact, the unit would be an excellent start for building a legal limit 3-500Z amplifier. Useful parts include the plate meter, input coils, pi-network output coils, tune capacitor, load capacitor, change-over relay, filament transformer, meter switches, fan, etc. etc. Let me know what you need and what you'd like to offer for it. Unfortunately, I cannot ship anything overseas.

Thanks for reading the posting.

73s,

Evan

349. Coded Signals In Radio & TV Broadcasts

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-11 03:50:56 UTC
From: ddmga@yahoo.com

I am participating in the ratings panel for Arbitron
(www.arbitronpanel.com). They gave me this equipment which captures
and re-emits coded signals in radio and TV broadcasts. The signals
are supposedly inaudible to the human ear. Well, I'm interested in
finding out the frequency used by this equipment and on radio and TV
and if it can be monitored and decoded using a PC.

I haven't found any information or programs to do this on the net.

The patent numbers on the devices are:

5,764,763 Apparatus and methods for including codes in audio signals
and decoding

5,483,276 Compliance incentives for audience monitoring/recording
devices

5,450,490 Apparatus and methods for including codes in audio signals
and decoding

Any ideas or information is much appreciated!

Because you're drawing more current through the power supply. The
higher the current, the higher the ripple, the higher the ripple, the
higher the AC through the cap.
```

=====
Your grid-dip meter probably has several plug-in inductors (coils).
You can 'extend' to the lower frequencies by making an additional plug-in
inductor with more windings.
Depending on the variable capacitor in your instrument,you might have to add
fixed capacitance inside the additional inductor.

Frank , gm0csz.kn6wh@ntlworld.com

Probably done much like the 19kHz stereo latching signal in FM
broadcasts or the CTCSS tones used in 2-way communications. Does the
unit re-broadcast? If so, a frequency counter or a scanner can find
the freq. Can it be decoded? Yes, of course but in what time and at
what expense?

It is (presumably) on FM at any rate, on a sub-carrier of
the broadcast frequency. It's known as RDS (Radio Data System)
and carries things like time, station name, type of entertainment
provided etc.

On TV it's Teletext/Oracle, carried on spare lines of the
625-line system.

I'm sure Google will provide Websites which gives more
informed information.

Well the OP is in the US AFAICT, Arbitron isn't the UK company doing ratings... I don't *think* the US have RDS on their FM services, could be wrong though.

I'm not sure which bit he wants to decode. The data on each TV/Radio station broadcast or the link from the Arbitron box to the personal meter. A neat arrangement if it is using ultrasonics so the meter only logs when the person is in the room, not the other side of a wall as would happen with an RF based system.

Yup. We have RDS. At least it is approved, but only 1/20 (or less)
FM broadcast stations actually transmit it. And of those that do
transmit RDS, most only send their call sign. Sometimes they
transmit the time, but of the two stations I can receive that do,
the time is almost always far off.

Steve , Like PMR446 (8 RF channels ,446.0025- 446.1025 MHz) in a number of
European countries , FRS involves type approved radios with a fixed antenna.
So homebrewing for these bands is prohibited.

As noted previously, Marty's project was the perspective of this discussion. When simpler concepts of earth borne surge protection are understood, then maybe we are ready to discuss aircraft. The same principals apply to aircraft - only more complex. Forget nonsense about aircraft and lightning that only confuses with irrelevant information. However, that picture demonstrates that even flying aircraft must shunt a lightning strike to earth ground.

For those distracted by irrelevant posts, Marty asked about building a surge protector only using three MOVs. Marty learned that a surge protector is one component of a surge protection 'system'. But the most critical component in that 'system' - the most critical component in his schematic - is central earth ground. A surge protector located far from earth ground is all but disconnected from the rest of the 'system'. Surge protectors don't stop or absorb surges as promoted by urban myths.
A surge protector connects (shunts) a surge to earth ground - the most critical 'system' component. No earth ground means no effective surge protection. Earth ground was missing in Marty's original schematic.

One of the best homebrewers I ever met was Ken Moore,
W6WIS (SK); he was a radio engineer for a major airlines
and I always admired his homebrew gear.

I never got around to asking him - he would put a little
dot of red paint on every point-to-point soldered connection -
has anyone ever seen this practice? Is it to indicate the
connection has been inspected?

My car radio has RDS, and at least one of the local stations (in Indy),
provides information such as music title, etc. I really don't
see RDS as being all that big a deal, but certainly helps with
the identification of music.

Hello. I need to ID a SMD part on my IC-2000H. It is on the front panel PCB, front side close to the power button 1/2" directly above the DS3 lamp. It is also slightly under the edge of the LCD panel. There are two sets of SMD pads one with a 1K (102) resistor on the left side and the other with the pads of the missing part. It is the same size as the 1K resistor and could be either a chip resistor or cap. Anyone have the service manual, schematic or have one they could look at and get me the info as to what part goes there? The radio received an impact and the little part fell off and is long gone. Also there is no part ID on the board at all. (i.e. R101, C201 etc.) I also need the pin out of the mic. connector.

Thank you,
Randy KB8ASO

I think so. About 50 years ago I worked for University Loudspeakers and
we put a drop of Glyptol on every connection. Let's see what other
people have to say.

It was common practice with WW2 gear. Look at an ARC-5 or similar rig
and you'll see the glyptal dots all over. Presumably it was to indicate
inspection, although I've never had this confirmed by someone who
actually worked on the production lines.

With your friend however, painting his own solder joints seems rather
pointless except for the nostalgia, perhaps.

Bill, W7TI

371. Radio, Electronics Parts, and Accessories!

Update!

Radio, long forgotten sense the advent of the TV, and now the computer
was the original source of entertainment for Americans for almost 75 years;
besides the morning traffic report, the radio is an obsolete means of
communication, and the science of radio a dead language... Years wasted out
the window.

Hi

At the present time, I'm offer a look into the inner workings of an
integrated circuit... FREE. And that's not all, for just $2.98 you can
download the specifications of a 1MHz wide-band Radio Receiver.

You can even add-on a directional antenna.

Sounds like the specs for a cheapo AM-BC radio. You can buy a whole
radio for $2.95 instead of just the specs.

When did Ken die? He was a friendly acquaintance. The last time I spoke with him he was around 90 or more.

I recall him recognizing me on the Queen Mary when I wanted to go into the radio room. It was off limits to the public but he invited me right in, very nice man. I don't know anyone who didn't like Ken. AAR9YV in Army MARS.

Apart from station name the other main use over here is Traffic News.
Listen to one station (from the same EON group) or listen to CD/Tape
and have any traffic news cut in when transmitted. Moderately useful,
the reliabilty of the actual information can be dubious and some
stations are notorious from "forgetting" to cancel the TA flag at the
end of the bulletin or keep it up untill the following advert
(unrelated in anyway even sponsership of the traffic news) has
finished.

I guess the EON only really works where you have many stations all
covering the same area and cooperating. Like the BBC with 4 national
FM Networks and many local stations.

=======
Yes I have seen 'inspection paint markings' on some military equipment and
also on Collins Aircraft HF Automatic Tuners ,the latter sold in the mid 90s
by a UK surplus equipment trader.
These tuners had excellent components incl a 1000pF -3000V Jennings vacuum
cap (motorised) , a motorised roller inductor and a Jennings vacuum switch
,besides some other components.
At the time they were sold for equiv US $ 80.-

I am providing information, including circuit board layouts schematics, theory of operation, etc, for high performance receivers, noise sources, preselectors, and whatever else comes to mind free of charge. Why would you be charging the folks on a homebrew newsgroup for this?
On another note.....that bank in Nigeria scam has surfaced again. Yesterday, I received an e-mail about some fellow with 30 millions dollars who had died, having no next of kin. The originator of this e-mail told me that all I have to do is give him all of my bank account information, and that 5 million dollars would be transferred to my account. Be careful with this one!

From: jim.bolinger@lintek.aeroflex.com
Message-ID: <8d5ec8a2.0206120437.6ecb6bc4@posting.google.com>
Source record: 43441

I'm talking about controling model airplanes.

I haven't done RC in 20 years and my equipment is out of date.

The FCC regs, as far as I can see, does not restrict RC to any particular band. All they say is 1 w max output and (I assume) bandwidth restrictions.

Two of my units are on 6 meters, but I think this is just a voluntary band plan started back in the days when anything above 53.999 MHz required black magic.

What I am wondering is if anyone was homebrewing RC equipment for any higher bands, such as 430 MHz, 902 MHz or 1.2 GHz, or even higher? With PICs and all the neat RF components I think it would be relatively easy, compared to 40 or 50 years ago (when 6 Mtrs use started). What bands would you recommend, and what modulation mode? Some type of digital encoded PM?

Ok, if I was restriced to 6 Mtrs, any ideas on upgrading my 20 year old equipment to meet todays specs? Transmitter upgrade would be easy, compared to the receiver, but for my 100 inch sailplane there is plenty of room for a small homebrew receiver. What I have is a Heathkit 5 channel PWM analog, and a 2 channel Cannon (same format).

FLEA all SUMMER at MIT
Sunday June 16th 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

Don,

Back in my Ham service days at Heath we used to drop glyptol into gear to prevent settings from changing due to vibration (on coil slugs and pots), and also on re-repairs where we were certain the equipment met specs when it left the shop, but would come back three weeks later... all out of alignment. If the gear came back a third time and the glyptol seals were broken, we would advise the tinkering ham that we would be happy to re-align his equipment for a fee, but the work would not be covered as a warranty repair. ;-)

Be VERY careful. The eventual goal seems to be to lure you to Nigeria (or
other foreign country), and kill you after getting enough information to
take over all your assets. People HAVE been killed.

Hm. Why polycarbonate capacitors, then? Perhaps high dielectric constant
for low-frequency use?

Par for the course. America always different to everyone
else in the world.

I expect that, in the land of unregulated capitalism, it doesn't
make a profit, so there's no interest in it.

It does a lot more than that. Most modern car radios will search
for the best signal with the same ID. Some can search for stations
of a particular type, or find stations broadcasting traffic
information. Not to mention carrying the time which, (in Vauxhall
vehicles at least) keeps the clock to within about 1 second
of the UK primary standard.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D079D50.3060603@eznec.com>
Source record: 43351

High frequency Q isn't important for a lot of capacitor applications. More important in some appications are such things as temperature coefficient, reliability, physical size, self-healing properties, and nonlinear properties like "soak" (dielectric absorption) and "hook". Various dielectrics are better than others at one or more of these things, which is why they come in such a variety.

Polycarbonate has low dissipation factor (i.e., relatively high Q), low dielectric absorption, high insulation resistance (relatively small physical size), and a very low temperature coefficient.

Polystyrene, incidentally, is one of the options. But it melts at 90 degrees C, so can't be metallized, which requires temperatures higher than this.

and I believed the main reason for introducing RDS is to broadcast
important information about traffic jam and accidents, and
particularly warn when somebody drives the wrong way on a motorway.
It is a lot of such warnings in Germany. Receiving such messages will
interrupt playing cassettes or CD's

In the US, there are few cases where multiple stations use the same
'ID.' For traffic jams, etc, cell/PDA based schemes are better.

OTA radio in the US is not a growth market :-).

Hi all,

I'm thinking about homebrewing a 10 meter beacon. I have a Maxon HCB-10C handheld cb that I'd like to try and modify for 10 meter and use it as my transmitter. I've looked on the internet and can't find any mods related to this radio. I was wondering if someone might could point me in the right direction.

Thanks
Matt

>>of a particular type, or find stations broadcasting traffic
>>information. Not to mention carrying the time which, (in Vauxhall
>>vehicles at least) keeps the clock to within about 1 second
>>of the UK primary standard.

Here in the USA a lot of that would be considered "poison" by station management.

A USA broadcasting license conveys authority for only one transmitter. Additional medium- and high-powered transmitters can be licensed, but are legally considered separate stations. They must compete with other applicants for the same frequency. Also, until very recently, a given company could not own multiple transmitters with overlapping coverage. Low-power (less than 250w ERP) transmitters are easier to license, but until recently they were limited to 10w, and still must compete for frequencies.

The result is that USA stations generally run as much power as possible at a single transmitter, rather than using multiple lower-powered transmitters.

So the ability to search for the best signal is usually useless, there is only one frequency for a given program.

Searching for a particular type of programming also probably wouldn't be very popular with management. There are three country-music FM stations here in Nashville, owned by three different companies. Others at the fringe of the city (where motorists would be going when the local transmitters fade out) are owned by several more companies.

Gaylord Entertainment sure doesn't want a radio tuned to 95.5 to suddenly jump to Clear Channel's 97.9 when the car goes around the wrong side of a hill.

Similarly, Clear Channel doesn't want one of their 97.9 listeners dragged to 103.3 when Cromwell's station decides to do a traffic report. (especially given the cited problems with European stations being slow to turn off the traffic flag. USA stations have been known to pull similar tricks with an emergency-alerting system called "EAS".)

==========

All that said, there *is* a lot to be said for EAS. I think radiotext may be the killer application here in the USA. In Canada there *are* large multifrequency networks (especially run by the CBC) which *could* take advantage of alternate-frequency information. And even in the States,

the use of multiple frequencies is growing.

Clear Channel, the largest station owner in the USA, has recently installed RDS equipment on their stations in one market as an experiment. If it succeeds one might expect major growth in RDS use in America.

==========

Unfortunately the other problem is getting parts. A few of us looked into building homemade RDS decoders. The standard chips are only available (in the U.S.) in minimum order of 50 - far more than interested hobbyists in America would ever use. Likewise for the crystals. Ended up being cheaper & easier to import some Conrad units from Germany. (unfortunately the PTY codes are different in America, we use a conversion chart...)

397. LMX2305 PLL and AD9835 DDS prototyping adaptor PCBs

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-13 09:23:43 UTC
From: Leon Heller <leon_heller@hotmail.com>
Message-ID: <ae9oau$k6m$1@helle.btinternet.com>
Source record: 43359

I've designed a simple prototyping adaptor (about 1" by .75") for the Nat. Semi. LMX2305 PLL chip (0.65 mm lead spacing),that can, with care, be made at home. The leads are brought out to a 20-pin 0.6" DIL pattern, and there are pads for two sets of 0805 decoupling capacitors. Double-ended pins may be inserted to produce a module that can used in an easy to make home-made PC. I'm in the process of building a PLL synthesiser with this module covering
about 50 MHz to 80 MHz using 'ugly' construction on a small piece of PCB material. For initial testing it will be programmed via the PC printer port.

I've also done a similar one for the ADI AD9835 DDS chip.

Details for both PCBs, including artwork files that can be printed on a LaserJet printer are here:

http://www.geocities.com/leon_heller/adaptors.html

I can get some (proper) PCBs made, if there is enough interest. Please email me for details.

Any "short circuit" absorbs energy. If enough energy transfers, the circuit itself goes up in smoke.

> In a properly sized surge protector,
> many times more energy is diverted through a shunt mode surge
> protector than is absorbed.

Indeed, and in so doing, by acting essentially as a short circuit across the voltage input terminals of the device being protected, it prevents the voltage energy being shunted from raising the input voltage on the protected device to destructive levels. What is it about this fact that makes it impossible for you to understand?

No one questions that a surge protector shunts to -or toward- ground the destructive energy involved. But to advise people to NOT use MOV surge suppressors is to advise them to just skip a very important level of protection. They DO work. Many times I've had the experience of being glad I had one installed when I had to replace it because *it* was destroyed instead of the protected device, after it did its job.

Source record: 43366

I've built a simple superhet xcvr that uses a MPF102 audio mute and a t/r switching scheme like the one on the SW+ series of radios. I'm getting a very annoying pop everytime the rig is keyed. I've upped the value of the cap at the gate of the MPF102 to .22uF (instead of the customary .1uF) and it helped a little.

I'm thinking that the choke to the final preamp might be the culprit (it's keyed with a PNP transistor). I've heard of putting a zener at the choke to prevent the collapsing magnetic field from causing a back voltage. Could that collapsing field cause the pop??

Does anyone have an idea where to look to solve the popping?

Tnx,

Bill

Is this a short, high frequency "pop" or a lower frequency "thump"?

Without seeing the circuit diagram I'm only guessing, but if it's a "thump" you may have too much low frequency response in the receiver. Try reducing the value of one or more coupling capacitors between stages or between the final stage and the speaker/headphones.

Poor power supply regulation can cause this problem. If possible, try running the receiver section from a separate supply and see if the problem goes away. If it does, you may want to install a separate regulator IC, either for the receiver alone or for both TX and RX.

Are you confusing RDS with Trafficmaster (Oracle)?

The 'TA' (Traffic Announcement) system on RDS works something like:

Participating stations set a flag on their RDS when (and only when)
they have a traffic announcement to make.

RDS scans all the stations it can hear for this flag.

When it finds one, it switches to the station with the TA flag
from whatever one may be listening to.

The flag is reset after the traffic broadcast and the RDS re-tunes
to the original station/tape/CD etc.

You can activate it or deactivate it as desired.

There's only one transmitter involved in RDS. It's impressed on the
single FM signal - only one transmitter needed.

>The result is that USA stations generally run as much power as possible at a

I see what you are getting at. Here we have 4 national, advert-free,
licence-fee financed programmes. This requires many FM transmitters
throughout the country carrying the same programming. So the system
works well.

>Searching for a particular type of programming also probably wouldn't be

Yes, but you only have to push the 'TA' button to clear it or push
the button of the station you were listening to if you don't want the
information, or if they keep the flag on too long. With steering-wheel
mounted radio controls, it's easily done.

>USA stations have been known to pull similar tricks with an

This is what happens when you have nothing but commercial
stations. Horrible!

So Clear Channel can keep people tuned to (different) Clear Channel stations as they move about, not randomly wander off to possibly (shock horror) a competitors station. This already happens over here with in the commercial stations owned by a group. Tune to a GWR group station and as you move out of range you'll be tuned to the next GWR group station, if there is one.

> Are you confusing RDS with Trafficmaster (Oracle)?

Trafficmaster is completely seperate and up to the minute (well few minutes) accurate. Radio travel bulletins can be as much use as a chocolate teapot. Which is why I gave up on RDS TAs and got a TrafficMaster YQ unit...

> The 'TA' (Traffic Announcement) system on RDS works something like:

There are really two systems, the basic and the EON (Enhanced Other Network).

On the basic system you can listen to a single radio station and only get TAs from that station. These will interupt the tape/CD you are listening to or raise the radio volume from zero to a preset level. The station simply raises it's TA flag at the appropiate time.

EON the station signals a central point that it is making a TA and this is the signaled back to all other stations on the Other Network. So you can listen to any (in the case of the UK. national) station[*] and get all TAs from many other (local) stations within range.

[*] Or listen to a tape/CD with the radio part tuned to a national station.

I have several handheld radios that need repairing. I can take these home for repair. I need to know within 3 weeks (but probably 2 weeks), or the job will be given to someone else. Also,you must be in Massachusetts.
Ironically, since I brought it up, now they want the repairs sooner. So, the sooner I can
find some help, the better.

Anyone with knowledge of radio electronics willing to do radio repairs? If you have the experience, but are not willing to do the repairs, please contact me as well. I would be able to compensate you for a 1 day appearance. Please email me if you want more details about this. Also, anyone that is just interested in working with these radios is welcome as well.

If you, or if you know someone that may be interested, please email me. My email address is vshah101@aol.com in case you are interested.

It would help if you posted the brand and model numbers.

416. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-14 06:00:07 UTC
From: w_tom <w_tom1@usa.net>
Message-ID: <3D098667.7C0573E8@usa.net>
Source record: 43379

The only short circuit that absorbs energy is one that really is not a short circuit. Ideal short circuits absorb no energy. Where did you take your EE training? Imperfect short circuits only absorb a minor percentage of energy. If the purpose of short circuits were to absorb energy, then the purpose of all electric company wires is also to absorb energy. Obviously not. Ideal short circuits absorb no energy. Better, real world short circuits absorb all but no energy.

To say the purpose of a short circuit is to absorb energy is to not understand basic EE principals and therefore to not understand how surge protection works.

Like the imperfect short circuit, the MOV does absorb a minor percentage of energy. But absorbing energy is not its purpose. The purpose of MOVs and other shunt mode surge protectors is to shunt - transfer energy elsewhere.

If an MOV shunts a common mode surge across wires to an appliance, then the adjacent MOV has only provided that common mode surge with more paths to earth destructively through an appliance.

> What is it about this fact that makes it impossible
> for you to understand?
Again you are describing a differential mode surge. Why to you also have a problem with this basic EE concept? Why do you confuse normal mode vs longitudinal mode transients as if they were same?

Put all MOVs across all the AC inputs to an appliance - and the common mode surge will simply fly past them on its way to earth ground through the appliance. Even better, short all the AC wires together with wire. Still the common mode surge will pass by on its way, destructively, through appliance to earth ground. Somehow you keep thinking that a common mode transient is just like a differential mode transient.

If that MOV worked across AC inputs to appliances, then why do appliance manufacturers not install them? Answer to that question is essential for your claims of protection to have any credibility. Those MOVs are not installed inside appliances because they are not effective when too close to transistors and too far from earth ground. Even your own example demonstrate no effective surge protection. All that

was proven is a grossly undersized surge protectors was
damaged by a surge too small to even damage the appliance.

If your surge protector across AC inputs worked, then in
engineering terms, where did the surge go? What was the
incoming path and what was the outgoing path? A 100 amp
common mode surge approaches the appliance. What does that
MOV across the AC inputs do? This is basic engineering. To
say that a surge protector worked demands that you can say
why? What was the incoming and outgoing path of that surge?

Maybe you can explain to me what I am doing incorrectly.

On pages 36 and 37. Under the topic of Insertion Loss. Figure 2-16. Rs = 1000 ohms, RL = 1000 ohms, L = 0.05 uH, QL = 10, C = 25 pf, Qc = infinite. So Q = QL. Resonance occurs when omega^2 = 1/(L*C). So omega^2 = 1/(((0.05)(10^-6))*((25)(10^-12))), or omega = 894,427,191 rad/s. Rp = Q*Xp. Xp = L*omega (or 1/(C*omega)), so Xp = (0.05)(10^-6)*(894,427,191) or Xp = 44.72. So Rp = 10 * 44.72 = 447.2, or roughly 450 ohms. Mr. Bowick states a result of 4,500 ohms. So I am off by a factor of ten. Can you tell me what I am doing wrong?

Thanks

Mike

It's definitely a high frequency pop...not a thump. And it happens on
key down..not key up. It'll take me a couple of days to draw up the
schem but I can send to you if that'll help. Increasing the cap at
the gate of the MPF102 only helped a little. I'm wondering if one of
the T/R diodes is bad and letting too much RF through?? Not sure
what's going on but ur regulation suggestion is worth looking into.

Tnx,

Bill

For any particular station only one transmitter is needed
I meant. In any case I misunderstood what he was getting at.

He he. Yes. I understand some leave the flag set to boost their audiences.

I don't use the system as I have Trafficmaster, which is more specific to the road I am on.

My Vectra had EON (and Trafficmaster). New car doesn't state whether
EON or not. RDS doesn't set the clock either, as the Vauxhall did.

Skippy,

Where did I say it didn't "meet FCC requirements"? There are
thousands of linear designs (albiet mostly UHF/VHF that use
4CX250s). I only pointed out
that as far as IMD performance, there are much better ceramic
tubes available than the 4CX250.

Enlighten us.

I don't think so. We did have a process for varnishing the entire chassis for use in the south pacific (high humidity) but just coating the joints would not due much if the joint was well made to start with.

Hello,

This great valve databook is still in stock, but it will now be soon
out of print and difficult to obtain. 660 pages with comprehensive
data on nearly 6000 types - European, Russian and American
manufacture. A lot of curves and operation conditions on each type.
This is a very large book of 29 x 21cm and the weight is 2.5kg
You can find more information and pictures of it at my web site
www.demostenes.no

Regards,

Arnold Goks�yr
DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://www.demostenes.no

Thousands of different valves in stock as well as
sockets,transformers,books,caps,resistors and
other components. Web site is updated every week.
You can order on-line.

Hi Philip,
Actually, I do have MW only version of this unit. I may be
writing a couple of articles; one of them will be for the general converage
version, while the other will be for the MW only version. The nice thing
about both of these designs is that the MW only version requires only one
adjustment, while the general coverage version requires only two.
I just need to get the final ok from my employer for release of the
articles. The first release will be using an Analog Devices AD9851 DDS for
LO injection; the next generation will use a hybrid version, incorperating a
DDS as a variable reference in a PLL circuit, using that circuit as a
tracking filter. I expect to have that design done sometime around
September of this year.

Yes, it is a good idea to have two. They won't drop out out lock and
go to UNLEVELLED simultaneously, so it is a good chance that one will
work while the other makes a nuissance
Mine are model 3001, but they are all the same rubbish, believe they
cover the range 1-560 MHz in 1 kHz steps with considerable residual FM

HHaaaaaaaa haaa!! I have two 3001 dogs as well. Complete garbage.
They should lock in under 5 seconds, BTW. As Jan-Martin notes:considerable
residual FM, and a horrific noise floor--not much good for blocking or
IMD measurements. You need two to keep one running. I've rebuilt
several of the modules, am continually replacing shorted tantalums, and
find
owning the units is a good excuse to buy a 2-GHz counter and a spectrum
analyzer just to troubleshoot and align the beasts.

I have a Wavetek 3001 that also took about 15 minutes to stabilize...

When it finally broke the rest of the way I took it apart and found an electrolytic capacitor failed. It appears that it was leaky and it had to be warmed up to work which caused the 15 minute delay.

I went through and replaced the electrolytics. After that, it does indeed lock up in just a few seconds.

A 15 MHz scope should have a usable response above that frequency,
with loss of vertical calibration--not a serious matter for your
application.

Good luck. I've had past experience (pretty much all bad) with
Wavetek gear. I'm surprised it goes for the prices I see on E-pay.

I refused to use any Wavetek equipment at my last job, and the old man in the Cal Lab didn't want to repair the crap when it died. The only thing they made that I liked was a couple of their dual concentric shaft stepped 10 Db / 1 Db attenuators.

That's because the buyers haven't used Wavetek before! Even worse
was the garbage they made for CATV work. A so called scope with a 12
inch monochrome green screen monitor tube to align amps and converters.
Several of their crappy sweep generators were sold for that as well, but
were 50 ohm, and all the equipment in CATV distribution is 75 ohms.

He did not mention "Ideal short circuits".

> Where did you take your EE training?

You don't even understand ohm's law and you're attempting
to discredit him with a snide question?

> Imperfect
> short circuits only absorb a minor percentage of energy.

Bullshit. Drop a #20 bare wire across an energized
20 amp household circuit. What vaporizes? What absorbed
the energy?

> If
> the purpose of short circuits were to absorb energy, then the
> purpose of all electric company wires is also to absorb

How can anyone have a rational discussion of anything
related to electrical issues with thinking like that?

>
> To say the purpose of a short circuit is to absorb energy is
> to not understand basic EE principals and therefore to not
> understand how surge protection works.
>
> Like the imperfect short circuit, the MOV does absorb a
> minor percentage of energy.

Which is a reversal of your earlier position that MOV's
absorb NO energy. An MOV clamping a voltage at 330 and
conducting a 100 ampere surge absorbs 100*330 or 33,000
watts. Whether or not that is a minor percentage of the
energy is not key. What is key is that the equipment
the MOV protects "sees" only 330 volts, as long as the

MOV continues to work during the surge. Where the surge
energy goes doesn't matter to the equipment, as long as
it doesn't "see" the damaging high voltage. You never
mention this.

? But absorbing energy is not its
> purpose. The purpose of MOVs and other shunt mode surge
> protectors is to shunt - transfer energy elsewhere.
>
> If an MOV shunts a common mode surge across wires to an
> appliance, then the adjacent MOV has only provided that common
> mode surge with more paths to earth destructively through an
> appliance.
>

Bullshit. You earlier specified that in your view
a common mode surge can enter the house service panel on
a single hot wire. The MOV connected from neutral to hot
in a point of use protector protecting your refrigerator,
clamps the voltage across line and neutral to 330 volts.
Where are the destructive paths through the 'fridge?

You always misuse the term common mode. If you want to
make yourself clear, describe what you have in mind
when you use the term. Give us the voltages between
each point in the circuit that you envision so we know
what you are talking about.

> > What is it about this fact that makes it impossible
> > for you to understand?

It is not a fact; you misuse "common mode" so no one can
understand you; you ignore the protection afforded when
the MOV clamps the voltage across hot and neutral to
~330 volts.

> Again you are describing a differential mode surge.

Yes he did. And you completely ignore it.

> Why to
> you also have a problem with this basic EE concept?

He understands it - you do not.

> Why do
> you confuse normal mode vs longitudinal mode transients as if
> they were same?

He did not confuse them - he specified the surge he was
talking about. It is you who confused his description
of a differential mode surge. Lord only knows what *you*
think a normal mode transient is, but if you use the terms
properly normal mode = differential mode, and common mode

= longitudinal mode.

> Put all MOVs across all the AC inputs to an appliance - and
> the common mode surge will simply fly past them on its way to
> earth ground through the appliance.

Bullshit. The common mode surge elevates both the neutral
and the hot wires. But the neutral wire is elevated far
less, because it is connected to the grounding electrode
via the grounding electrode conductor and main bonding
jumper. Therefore, the hot wire is elevated far higher
than the neutral wire. That means that there is a differential
mode surge that could be "seen" by the appliance.
The MOV's will clamp the voltage that the 'fridge "sees"
to ~330 volts. The case of the fridge is connected to
the same place in the service panel as the neutral, via
the equipment grounding conductor. Unless there is a defect
in the 'fridge, there is no internal path for current to
flow to the case of the 'fridge. In addition, an external
point of use MOV connected hot to ground clamps the hot
to case potential to ~ 330 volts if a surge causes it to
switch from very high resistance to low resistance.

> Even better, short all
> the AC wires together with wire. Still the common mode surge
> will pass by on its way, destructively, through appliance to
> earth ground.

Show us the path. We've got the neutral, hot and egc
shorted together at the receptacle into which the
refrigerator is plugged. A common mode surge occurs
and enters your service panel. What is the destructive path
through the fridge to ground?

> Somehow you keep thinking that a common mode
> transient is just like a differential mode transient.

He has made only one post in this thread, so any observation
by you that he "keep(s) thinking" something is not supported.
But that is not the problem. He SPECIFIED a particular
surge, and you insist on trying to twist it to something else.

And aside from that, you do not understand a common mode
surge to begin with. You seem to think that any surge
that "seeks ground" automatically precludes a differential
mode - hot to neutral - surge. In fact, any common mode
surge entering your service panel will be a differential
mode surge on the hot and neutral branch circuit wiring
in a grounded service.

>
> If that MOV worked across AC inputs to appliances, then why
> do appliance manufacturers not install them? Answer to that

> question is essential for your claims of protection to have
> any credibility.

Absolute fucking bullshit. 1) MOV's are included in some
equipment, so your premise is FALSE. 2) Whether or not
an appliance manufacturer includes a particular component
or not has nothing to do with whether or not that component
can provide a particular function that is not essential
to the appliance's operation or acceptability for market.
Your logic is totally bizarre.

> Those MOVs are not installed inside
> appliances

False premise. They are in some appliances.

> because they are not effective when too close to
> transistors and too far from earth ground.

False. You ignore differential surges; you assume
transistors.

> Even your own
> example demonstrate no effective surge protection. All that
> was proven is a grossly undersized surge protectors was
> damaged by a surge too small to even damage the appliance.

Howinthehell do you know the surge was too small to damage
the appliance? Like the rest of your unsupported statements,
your thinking boggles the mind.

>
> If your surge protector across AC inputs worked, then in
> engineering terms, where did the surge go?

How many eff-ing times will you post this drivel? The
protector absorbed enough energy to destroy it. You
earlier admitted he was talking about a differential
mode surge, and now twist it to common mode. Ok,
lets use your common mode surge, specified at 100
amps, which "approaches the appliance", and his destroyed
supressors, since you insist it had to be common mode.
There, it encounters two MOVs, one from neutral to ground
and one from hot to ground. Each clamps the voltage
to 330 volts. We don't know the individual currents,
all we know is that there is a path that causes 100
amps to be drawn. But we do know the total amperage
across them is 100 amps and the voltage across them is 330
volts. Therefore, at the instant in time where 100 amps
is flowing in the circuit and the MOVs are clamping the
voltage to 330, the combined wattage is 33,000 watts.
If you want to make the math just a bit messier, consider
the protected appliance. He did not specify - I will.

It is a 60 watt TV with rabbit ears. The path for
the common mode surge is "the outside world" into the
service entry panel. From there, it follows the
grounding electrode conductor to the grounding electrode
system. Some of the energy is dissipated in the grounding
electrode conductor, some is dissipated in the ground and
some in the electrode system. So far, all of that energy found
its path from the neutral wire feeding your house -
none of it from the hot wire, since the hot wire is
not connected to the ground system. The result is a voltage
drop across the neutral wire feeding into your house,
without a corresponding voltage drop in the hot wire.
This creates a DIFFERENTIAL surge at the service panel.
In your specification, there is at least enough energy
"left over" to allow a 100 amp current flow towards the
appliance. It does so across the neutral and the hot wires,
as a differential mode surge. The TV at the end of the
circuit is connected to only those two points - there
is no other available path, aside from the MOV point of use
protector. Considering the part of the surge you mentioned,
the 100 amps that approaches the appliance - the path
is simple: from panel via hot wire to mov to panel via
neutral wire. And, as mentioned earlier, from panel neutral
to ground via the grounding system. In the path, energy
passing through the MOV is absorbed in accordance with
ohm's law. It is also absorbed in the hot wire and the
neutral wire and the ground system - all in accordance
with ohm's law. You have never grasped this concept. You
seem to think diverted energy does nothing but somehow
"flow into" ground. You seem to think that all of the
energy in a surge must be "returned to ground" as
an electrical charge. Not so. In addition to "charging
ground" (i.e. raising the local ground potential),
electrical surge energy can be, and is, converted into
heat in the wires, the MOV and ground itself.

Your continued erroneous postings on the technical aspects
of this destroy any good points you want to make.

What was the

Not quite the same as a website, but Amazon has a book by Gottlieb called "RF Power Design Techniques" that's not too bad.

w9gb mentioned RF Parts for parts. They are about the only place around to get RF power transistors, but their prices are pretty unpleasant. Still, if you need something as simple as a 2SC1969 or a dipped silver mica cap, I'm not sure where else you could go.

However, some designs rely on more mundane parts. A lot of amp designs use power MOSFETS and I noticed recently that B.G. Micro has some pretty impressive parts for very good prices. MOSFETS are relatively easy to toast but at a buck a piece you can afford to sacrifice a few to the cause. Bipolars are a little easier to deal with but their low input impedance makes it tough to get a lot of power gain.

In either case, keep in mind that 200 watts translates into quite a pile of 12 volts. I assume this is for SSB (25 watts on 10 meter CW is more than adequate) then you are probably talking about at least 30-40 amps for a class A amplifier. Not insurmountable, but certainly a few sheckels.

..

I would guess that you have already been told by someone who knows better that when 10 is dead a million watts won't get the message thru, and when it is hot 5 watts will do?

Working from my car (apt doesn't allow antennas) my htx10 (and my htx100 before it) have worked the w1oj repeater from Texas, worked as far east as the Ukraine, and as far west as Japan. 25 watts will go further than the receiver in the htx10 can listen (not nearly as good as the 100).

If you are using it from a fixed location, you are better off putting your money into a good 4 element quad antenna., I worked a fellow in Hawaii who also was using an htx10, he was using a quad from his house, and I had the whip on the back of my car, and this was back when the 10 was first released, before 10 meters peaked.
thanks, John.

I've got two Marconi 2019A sig. gens. They are very good (they used them at Racal where I used to work) if a bit heavy, especially as I got one for a fraction of the usual price at a radio rally because the seller thought it was faulty. I thought it might do for spares. It was just set up for external ref. input, which generated a fault condition when it didn't get it. He had another one with the same 'fault', I would have bought that as well if I hadn't checked the one I bought until the next day. 8-(

Hi,

I am busy of remaking a design of the Unichip tranceiver from G3MY. Some yeares ago has PA0WDW wrote about this simple TRX into the club-magazine of THE BQC Benelux QRP magazine.

In this design there is used the CA3046 (CA3086) and a handfull of other components.

PA0WDW have made sevral changes and know its a very good working rig.

There is only one dispite and that it is only to be used for CW.
On this moment I am busy to modificate it so it can also work with DSB, and that only achanging the mixer and adding some capacistors and inductors. The basic is still the use of one chip for the basic design 100mW and with adding one RF trasistor a 2N2219A booting it to about 1 Watt.

The layout for it is almost ready and will be made onto a short term.

I would like to know if there are other Hams who have made this simple rig and if he had made also some modifications to it.

If there are also other ones who also want to build it with all modifications of PA0WDW and those of mine to work onto phone (DSB), please let me know as we can share the results and or next modifications to get a even better design.

These design will also be placed onto my wbsite, a link to these site is to found onto www.qsl.net/pa3cmd

Basically the rig is only to be used for 80m, so I am also busy to make a kind of adapter to that it also will work onto onther. The Idea is to make several Adapters for all those band what I personal find interesting as 10, 15, 6 metres.
And that all with a max power of 100mWatt (1 Watt)

Eim.....PA3CMD

Patrick

John kind of echoed some thoughts I had this morning.

If you are talking SSB, and if you are talking paths of, say, over 500 miles, then going from 25 watts to 200 watts isn't going to help much on 10. In fact, I'd be surprised if you could see any difference at all.

On 80 and 40, atmospheric noise and absorption mean that power can be used to overcome the path loss. On 20 phone, the noise is from a lot of strong stations, so power can help overcome that deficit. But on 10, propagation is dominated by sporadic E, which is very low loss, and F skip, which is limited by E layer absorption, which on 10 is virtually nonexistent. The band isn't crowded enough that you are really competing with the kilowatts.

If you aren't having a lot of success at 25 watts, then I would look elsewhere in your system for the solution. The one or two S units you will gain from going to 200 watts isn't going to be worth the trouble. On 10 CW, a couple of watts is more than adequate, and on SSB, 5 or 10 will generally do the trick. FM is a little more power hungry, so more power may be a LITTLE help, but it's not going to be huge.

Now if you are talking about much shorter paths, then maybe power can help. For paths <100 miles, a little more antenna height will help a lot more than power. Again, tho, if you are looking for relatively local FM contacts, then maybe the power is the answer. But if you are looking for contacts in that 100-500 mile range, then power can be a big deal. There, tho, I would be looking for a full gallon, and lots of antenna gain. Even so, contacts will be few and far between.

As John also alluded to, openings on 10 are fairly rare. Es openings are going to occur when the flux is fairly high and you are about 400 miles from a thunderstorm, which makes it a late spring/early summer phenomenon mostly. F openings will occur when the flux is very high and generally in the middle of the day at the path midpoint, so European openings are going to tend to be in the morning. On top of the 11 year cycle the sun has a rotation that is approximately monthly. You will see a similar cycle in openings, but there is a lot of randomness in both the flux and the openings.

If you make a habit of checking http://www.qrz.com/solar.html every day, after a while it will become obvious to you what sorts of propagation to expect. Keep an eye on the flux, which will give you an idea of where the MUF is likely to be, and the A and K indices. When the flux starts to get up around 200, 10 meter F openings are going to be frequent. At 150 or so, Es openings are likely if you have a well-positioned thunderstorm. If A and K start to get very high, noise may become an issue but that is pretty rare

on 10. Indeed, high A index numbers could be a harbinger of interesting 10 meter propagation, while on the lower bands, they mean it's time to watch TV instead. The warnings of space storms are interesting because although they often cause HF blackouts, the time before and after they hit often involve unusual propagation, and the HF blackouts are rarely severe enough to affect 10, so there could be some real DX opportunities around those times.

Hope this helps...

..

www.bec.co.uk

BEC are the UK importers for TOKO, and the whole catalogue is on-line.
BEC hold stocks of some items while others (very similar) are on 6-week
delivery from Japan, so you'll need to phone to check availability and
maybe think about substitutions. BEC are happy to accept
credit/debit-card orders from private individuals.

I try to keep up-to-date details of all UK component suppliers on the
'In Practice' web site at www.ifwtech.co.uk/g3sek/in-prac/components.htm
Please let me know if you discover anything new.

> Or is there a better material to use?

Yes, but you won't cover the whole 28-29.7 band with one whip.

The Q of such an antenna is very high, and could also pose problems with power, at high RF input power they act like tesla coils and will corona like hell, or melt and catch fire from the circulating currents.

If you can add a plate to top-load the whip you can drop its Q you can prevent this. Best to start with a chunky whip, braided windings to handle the power and a thick former for lower Q and broader bandwidth.

Those ones with adjustable tips can tune the whole band if you take off turns from the top and reconnect them to the tip holder.

That hasn't been my experience. A whip of around 8 feet length is an almost perfect antenna, and ceertainly very cheap.

I have never had corona problems and the bandwidth is excellent. No, it doesn't cover the entire band with low SWR but very few people want to cover the whole band. Typically, you get one third of the band, which is more than enough for ordinary operations.

28.0-283. CW
28.3-28.4 Casual conversation
28.4-28.6 More interesting stuff, like DX and more profound things
28.9-29.1 AM operation
29.5-29.7 FM, repeaters

I adjust mine to cover from 28.0 to 28.6 and a simple whip does an excellent job.

If you decide to operate outside the limits of the antenna, there are a few solutions. One is a tuner. Another is a clip lead to add some length (if adding is what you want).

Sorry, I mis-read the original poster, re the 8-feet, figured he was talking about short-helicals. On my stainless whip I get about 600-800 kHz 2:1 bandwidth, with fat helicals getting 300-400 kHz if they are lucky.

Pat,

The case you are talking about is totally different than the
circumstances alluded to by others.

They are talking about contacts when propagation is good, noise levels
are low, and there is no QRM.

You are describing a case where power and antenna is very important.

In the case where propagation is poor (that happens on ten meters,
even though some of us pretend that it is like a switch that is either
"on" or "off"), noise levels are high, or other staions are calling
even the slightest amount of power increase can make a profound
difference in results.

So while there is some truth in the idea that small or poor antennas
and low power will work well on ten meters, that general statement
only applies when propagation is good and the receive station has no
noise or QRM.

In a case where you are about even with noise or QRM, even as little
as 1dB can make a noticable improvement in readability. On the other
hand 10dB improvement would be unnoticable if you are already 20 dB
out of the noise or QRM.

I went the tuner route when I changed from an htx100 to an htx10 in the car,
but one other option has always interested me.

Has anyone tried putting one antenna in the back of the car cut to cover
28.1-.5 and another antenna cut to cover 29.5-.7 in the front of the car.
Using an antenna switch if you pick the rear antenna, the front antenna will
somewhat act as a director, if using the front antenna, the rear antenna
will act as a reflector. Point the car in the direction you are trying to
communicate (preferably not while going down the highway) and it becomes a 2
element antenna. You may lose more in the antenna switch than you gain with
the second element, but I have always wanted to try this.
thanks, John.

>> I need advice on how to put together a mobile antenna for 10 meters.
>> Should i use a cb whip and cut it to the poroper length?(around 8FT)
>> Or is there a better material to use?

The 8 foot whip would be the best overall. On 10m it is a full quarter wavelength, so your efficiency would be quite high. That's the problem on the lower bands where mobile antennas are much less than quarter wave. Low efficiency.
>Yes, but you won't cover the whole 28-29.7 band with one whip.

He would cover a large portion, which should make any mobile ham happy. My homebrew 40m mobile covers 40khz and I am quite happy, after all I am mobile. 1/4 whip on 10m- 300-400khz?
>The Q of such an antenna is very high, and could also pose problems
>with power, at high RF input power they act like tesla coils and will
>corona like hell, or melt and catch fire from the circulating currents

Good grief, how much power do you run on 10m. When the band is open, 25 watts is plenty. If the band is not open, then most hams go to one that is, or turn their radio off. The only people that run enough power mobile to cause corona problems are cb'ers trying to run 10,000 watts into a 1/4 whip on 27 mhz. A Tesla coil is a 1/4 wave antenna, and a 1/4 wave whip on 10m is a Tesla coil. A 1/4 wave vertical is current fed at the base, where the voltage developed is minimum. At 90 degrees or 1/4 wave the voltage is at a maximum which is coincidently the Tesla coil principle. The big difference is the frequency that the two operate. T coils run around 200-600 khz depending on how big a coil you got. These are solenoid coils, but still 1/4 wave resonant. An 8 foot whip on 10 is 1/4 wave resonant.
>If you can add a plate to top-load the whip you can drop its Q you can
>prevent this. Best to start with a chunky whip, braided windings to
>handle the power and a thick former for lower Q and broader bandwidth.

I have no idea why you would want to do all that. A 1/4 wave whip for mobile on 10m sould be about a good as it gets. Easy to mount, easy to tune, works good, and wide bandwidth. BTW this question should have been posted on the RRAA antennas group. Probably get many replies and lots of interesting discussion.

Dear Hans,

I want to thank you and everyone who had responded to this call for papers.
The information will be of great help to me in class and on my web site.

Best Wishes,
William A. Wetzel

Dear Mike,

Yes... I have been using some of the Radio Shack books already. They have been a great asset in class for our projects. I hope they keep publishing them :)

Best Wishes,
William A. Wetzel
http://www.circuitsandparts.com

Mike Hall <wb3fup@webtv.net> wrote in message news:16356-3D08A1F8-105@storefull-2335.public.lawson.webtv.net...
Go to Radio Shack, they carry books called "Engineer's Mini Notebooks" that are full of what you are looking for. They used to be limited to a single subject (555 timers, for example) but now two and three of the phamplets have been combined into one larger book.

Calling For Simple Circuits For Student Projects

Group: rec.radio.amateur.homebrew Date: Thu, Jun 13, 2002, 8:20am (EDT+4) From: n6rky@circuitsandparts.com (William A. Wetzel)
For all the experimenters at large:
I am an electronics distributor during the day, and a part-time college instructor at night. Most electronics stores do not serve students and/or electronics enthusiasts very well in my area. I am setting out to change that (at least in a small way) over the summer.
I am looking for nice simple projects for students to build, especially those which are Amateur Radio related. Besides drawing some from the ARRL publications, I'm hoping to incorporate many from the "traditional tinkerers" at large. If you have a special project that you are especially proud of, which you want to live on... I would be most happy to hear from you.
Best Wishes,
& 73 de N6RKY

==========

Rubbish ! Piffle !

The Q of a 1/4-wave whip at 29 MHz is quite low, around 8, 3dB bandwidth roughly 29 / 8 = 2.5 MHz.

Prune it to resonate at about 28.8 MHz and away you go. But you won't get a 1:1 SWR without a simple L+C tuner at the bottom.

Or if you are pernickerty, just get a vertical of some sort, prune it to be 1/4-wave resonant roughly around 29.4 MHz, and when you want to work between 28 and 29 MHz just use a crocodile clip to add on a few more inches. Extending sideways is quite OK.

Or use a thick copper wire at the top which will stay in position when bent.

Or to do a nice job, put the top few inches on a hinge which will increase overall height when out straight and decrease overall height when the top few inches are hinged back near to the main rod or whip.

Again, if you are very pernickerty, a tuner will be needed for exact 1:1 SWR. But if you are interested only with the 10 meter band a tuner should not be necessary.

Most transmitters will work fine with an SWR not greater than 1.5:1 Perhaps more.

You should be able to do the job in less time than it takes to make enquiries on this newsgroup. ;o)

Enjoy your experimenting.

I missed the 8-ft bit in the original post, hence I figured he was talking about fibreglass helicals, which suffer the tesla coil problem even with only modest power. Your average $10 one is wound with pathetic wire as far as efficiency and power handling go.

I've never had an issue with corona on full-height verticals, only cheap and nasty CB whips run with stupid power levels. As you say, it is mainly a problem for the chook bander with a massive amplifer in the boot.

I have had bandwidth problems though, and a top hat helped.

There is no reason to limit Tesla coils to LF/MF, you can happly make them work at any frequency, with some engineering advantages for flash over as you go higher, but increased losses as well.

The 3001 has indicator LEDs which gave me a clue as to which module was the culprit... And it may have been a tantalum that failed. It was quite awhile ago, but it was either an electrolytic or a tantalum.

Fortunately, I had the service manual and I was able to troubleshoot to the exact component.

487. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-17 00:11:45 UTC
From: w_tom <w_tom1@usa.net>
Message-ID: <3D0D2940.E64BE95D@usa.net>
Source record: 43250

ehsjr does not do math before insulting others:

A #20 AWG dropped on a 20 amp circuit breakered circuit does not vaporize. The circuit breaker trips first. ehsjr would have known that if properly educated. Why? The 20 AWG copper wire has a fusing current of 58.4 amps. Again, basic EE facts.

But lets say a 100+ amp 120V circuit is short circuited by one foot of 20 AWG copper wire. 58.4 amps in that short circuit means that 0.592 volts appears on that wire as it vaporizes. Where are the other 119.41 volts? Elsewhere in the circuit. A 1 second short circuit dissipates only 34.6 joules in the wire AND 6970 joules elsewhere in the circuit. Clearly that shunt does not absorb the surge. As a nearly ideal short circuit, it absorbs nearly 0 joules of energy.

According to ehsjr, 7000 joules would be "absorbed" by a one second the copper wire short circuit. Reality: 99.51% of the surge energy created by a 20 AWG shorting wire is absorbed elsewhere.

MOVs operate same. They also shunt surges. Most of the energy shunted by an MOV is absorbed elsewhere. ehsjr would have us believe that an MOV absorbs the entire surge. What nonsense! ehsjr also would have us believe the vaporized 20 AWG wire also absorbed the entire transient that vaporized the wire. In reality, the wire is vaporized only by 0.49% of the energy involved in that short circuit. If the wire were an ideal short ciruit, then it would have absorbed 0% of the energy.

ehsjr must not have any EE training. He thinks a 20 amp breaker would vaporize a #20 AWG copper wire - because he fails first to do the numbers. Where does he get these ideas? Comic books? Super hero movies?

The same person who says an MOV absorbs surges also implies that differential mode and common mode transients are same. He also said so in previous threads. I have been through this same discussion with ehsjr repeatedly for many years. He still insists that 20 AWG wire short absorbs all the energy. I don't expect him to change. However his errors are cited for the benefit of others. His erroneous use of electrical principals is why he also thinks plug-in surge protectors can be effective. One thing that has changed is he is now

resorting to insults because of his insufficient engineering
background.

It does not take an engineering degree to first obtain
numbers. However when one thinks a 20 amp circuit breaker
permits a 20 AWG wire to be vaporized, then doubt that poster
has any EE training. When the poster thinks a wire shunt
absorbs all energy that passes through it, then we know it is
science fiction. Science fiction from someone who has no
credibilty criticizing another's education especially when he
cannot even perform basic math correctly.

That is not correct. It takes a finite amount of time for the wire to
melt, and the power would divide between the resistance in the wire
and the ESR or impedance of the rest of the system outside the wire.

> According to ehsjr, 7000 joules would be "absorbed" by a one
>second the copper wire short circuit. Reality: 99.51% of the

The truth is we don't know what the surge current is because we don't
know what the system ESR or impedance is outside the wire loop.

> MOVs operate same. They also shunt surges. Most of the
>energy shunted by an MOV is absorbed elsewhere. ehsjr would

Not true, for the reasons given above. Power divides according to
system resistances, and surge current and power can be limited by
system reactances. Factually, neither of you can have any idea what
the total energy is and how it is distributed...because there are too
many unknowns. The energy dissipated in the MOV can range from near
100% of available energy to near zero percent.

>have us believe that an MOV absorbs the entire surge.

Of course it does not absorb the entire surge.

You are both wrong. The truth is the small wire absorbs somewhere
between 100% and *much less* than .49% of the entire tansient.

>ideal short ciruit, then it would have absorbed 0% of the
>energy.

Now that much is certainly true, because in this case we know the dissipation in the perfect short...no matter what the rest of the circuit is comprised of.... is zero.

I don't know how you got mixed up with helicals. Everybody makes a cock-up now and again. I do it all the time.

But I just made a more accurate check.

Height of whip or rod = 98 inches.

Average conductor diameter = 0.5"

Resonant frequency = 29.0 MHz.

Resonant input resistance = 68 ohms.

At resonance minimum SWR with respect to 50 ohms = 1.4:1

IF SWR is adjusted to 1:1 at resonance then bandwidth between SWR = 1.5:1 points is 1.3 MHz.

Bandwidth between SWR = 2:1 points is 2.0 MHz.

Which are wide enough to drive a horse and cart through.

But the perfectionists would be happier with a tuner consisting of a few turns on a coil and a small variable capacitor. CB-ers are quite happy without one.

The above figures will change several percent depending on size of vehicle the antenna is mounted on and the location of the antenna on the vehicle.

Basic message - fit the CB antenna and start transmitting. Look out for low road bridges.

Regards, Reg. G4FGQ.

Bandwidth between SWR =

Hi Reg,

How does it come out to 68 ohms? Is there that much ground loss from
the ideal 36 ohms?

Hi Tom,
I have kept a few in the junk box over the years- don't see anything
new. Seems today's broadbanded P.A.'s are all toroidal with high power
clad caps.
What exactly are you looking for, maybe I have something in the shop.

==========

As I said, I make cock-ups all the time.

I did the calculation on a center-fed dipole and forgot to divide by two.
It's the drink !

The feedpoint resistance of the decribed 1/4-wave resonant vertical, 10m band antenna is in fact 34 ohms. All the other relative bandwidth details are correct because they apply equally to both 1/4-wave and 1/2-wave antennas.

34 ohms is less than the 'ideal' 36.6 because of the 'end effect'. To bring the antenna into perfect resonance (zero reactance)it is neccesary to shorten it by a few percent. But shortening the antenna also reduces the radiation resistance relative to the antenna free-space 1/4-wavelength at the velocity of light. But you are probably already aware of this sort of effect.

The minimum SWR at resonance is then 50/34 = 1.5:1 but who cares !

Good to know somebody reads my stuff and thinks about it. Thanks very much for taking the trouble to point out what is quite a serious error. My lurking critics could have had a field day with it ! ;o)

The relationships between antenna length, diameter, resonant frequency, input resistance, are covered by program WIRECAGE which can cope with very fat antennas as used by wide-band TV transmitters.

See you around.

I seem to remember a graph in there of conductor diameter vrs bandwidth
for dipoles (and monopoles over large perfect ground). Near the bit on
scaling of tapered elements.

> I doubt that it does. I don't get my information from there.

Well, please enlighten the group, how did you arrive at that figure? I
am not doubting it, I'd just like to know how to work it out in general
for other bands.

> And if it does, how will you know it's correct ?

I wouldn't, but at least it might have some math alongside that I can
see has more rigour than a quoted figure on usenet. :-/ If I could be
bothered to dig out my ancient Radio Engineers bible it would probably
have it.

Not reading the original post completely :-(

9ft stainless whips are expensive and uncommon for the CB operator here, most use the 3-4 ft fibreglass whip, so the first thing that came to mind was a helical, and then I went and shot my mouth off about some experences I'd had the burning them up and having to rematch the short ones ever 50kHz.

> But I just made a more accurate check.
<snip>

You used one of the programs on your site?

Unfortunately I don't have DOS here, and short of installing dosemu or finding my old DOS 3.3 disks, I can't run thos programs. They look pretty damn useful, any chance of posting the source or the formulas on the site so I can wrap them in a bit of C and use them myself?

Ever thought of making a few pages up that do the calcs for people, just punch the numbers into the forms and out drops the results. I'll provide the hosting with dynamic support (ie PHP) if you like?

499. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-17 05:29:01 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3D0D7408.75A7CAC6@bellatlantic.net>
Source record: 43262

You did not answer a single question I posted. You
decided that the "What vaporizes?" question in "Drop a
#20 bare wire across an energized 20 amp household circuit.
What vaporizes?" was a statement, and did respond to that.
And you were wrong.

When you drop a #20 wire onto an energized 20 amp
household circuit, a small portion of the #20 wire vaporizes.
The sparks you see when the wire is first dropped onto
the energized circuit demonstrate that. The burn marks
on the wire and the places it touched demonstrate that.
You may even be able to smell the odor, which also
demonstrates that.

Every one of your statements to the
effect "ehsjr would have us believe ..." is incorrect.

Here's one of them, as an example:
"ehsjr would have us believe that an MOV absorbs the entire surge. "
Now take a look at what I said:
"In the path, energy passing through the MOV is absorbed in
accordance with ohm's law. It is also absorbed in the hot
wire and the neutral wire and the ground system - all in
accordance with ohm's law. "

This pattern is repeated over and over. Either you
do not comprehend what you read, or you just twist it
around in your effort to discredit the poster.

You have not answered any of the technical questions, but
you have implied that what I posted included the term joules.
In fact, what I posted not only did not use that term, it
did not include any mention of time duration. How in the hell
do you get 7000 joules from anything I said, when I did not
mention time or joules?

Quoting you: " According to ehsjr, 7000 joules would be
"absorbed" by a one second the copper wire short circuit."

It is clear that you either will not or cannot discuss the
subject intelligently: you do not answer the questions posed;
you misunderstand and misrepresent what has been said; you
attempt to discredit the poster rather than address the issues.
You have no credibility.

You have maintained for years that an MOV absorbs all the energy of the surge. Are you now conceding that most of the energy is shunted and not absorbed by the MOV? Are you now conceding that a wire shunts - does not absorb - the surge? MOV shunts surges like wire shunts a surge - distributing surge energy onto other parts of the circuit instead of absorbing energy.

When the first paragraphs has a 120 volt 20 amp circuit vaporizing a 20 AWG wire - an absolutely ridiculous absurdity - then why bother commenting further. First you must acknowledge that a wire, absorbing less than 1% of the energy, is not absorbing energy. It is shunting energy to be absorbed elsewhere. The MOV and the shunt wire do similar. They both absorb trivial amounts of energy while shunting major amounts of energy elsewhere. The purpose of an MOV is to shunt - not absorb - the surge.

When you insult others AND start every paragraph with words such as Bullshit, then clearly your responses are, again, not technical and no longer worth comment.

The MOV across two lead on a refrigerator motor shunt a differential mode surge. Meanwhile, a common mode surge comes down one or both AC lines, passes through the refrigerator, to find a destructive path into earth. One path may be via the linoleum tile or a concrete floor. Or the ice machine water pipe. Does not matter which one. If a common mode surge finds that alternative, destructive path to earth, then damage occurs. The MOV either does nothing because it does not see the surge, or shunts the surge over to the other AC wire so that a surge has more potentially destructive paths to earth.

Furthermore there is no reason for a significant surge to be at the refrigerator if 'whole house' surge protection is properly implemented.

Either way, the MOV does nothing productive. Stop thinking that a differential transient is a common mode transient. Until you deal with that basic EE fundamental of common mode vs differential mode transients, you will live in a mythical world where plug-in surge protectors are effective.

Talking about differential and common mode transients is useful for the equipment manufacturer when designing the lab measurement procedures, but it is not very helpful when analysing the complex situation when a large surge enters a building.

Assuming ideal ground earth and neglecting the effects of the ground bounce voltage (caused by the non-zero grounding electrode resistance and especially inductance when the steep surge hits) does not permit much usable analysis about the real world situation.

It's been a long time time since I saw new
slug-tuned coil formers offered for sale.
You might get some from one of the surplus
suppliers.

I use Toko 10mm coil formers for low power
stuff. For higher power levels, I use fixed
inductors on a T-50 toroid and variable C.

Let's just start over.

The main point, for anyone trying to glean some useful information
from this, is that we really can not calculate or estimate where the
energy is dissipated because there are far too many variables or
unknowns.

One thing we do know, is anyone who claims it is xx.xx percent of
system power or whatever does not understand the problem. Especially
if he thinks fusing current somehow limits system current to that
value instantaneously.

Do you agree?

>and have never heard of a coil that was "1/4 wave resonant".
>
>'Splain, please.

I am not a T coil expert, so I should have left those comments off. I have built exactly one. The way I understood its operation was that the secondary of the T coil is a 1/4 wave monopole base fed. The primary at the base of the coil is a parallel resonant circuit fed with a rotary spark gap.
Anyway, the one I built was a 3' tube 0f 4" pvc wound with as many turns of #22 enamaled wire as I had. I fed it at its base with a 250 watt variable frequency rf source against an aluminum foil ground plane. It was resonant around 500 khz as witnessed by an increase in rf current to the coil, and 1" blue arc produced at the top of the coil. My point was that I could get the same effect with a 468 foot tall vertical monopole worked against ground. The Q of the two structures would be quite different however. I was tempted to wind one and see how it would do on 160m but never got around to it. It produced enough rf to open my auto garage door. The coil was in a room right above the garage.

Another, not so well known source for solid state amp parts is Westgate
Labs in NJ. AFAIK they have the east coast franchise for Toshiba devices
such as the 2SC2979 etc.

Lee Martin in SC makes the Skywalker amp kits which have been mentioned
above.

Your 'buck a piece' MOSFET's above are only good for 6-7MHz. Real RF
Power MOSFET's which talk up to and beyond 30MHz are a 'Are you sitting
comfortable' sort of price.

200w will not hurt a 12v supply as long as there's some kind of trickle
charge. Remember it's peak power you're quoting, not average which is
far less.

My Metron amp has 8 devices and only peaks around 70A for 5-600w out.

Now the Skywalker 8 device amp is over 100A!

Good luck.

I am receiving multiple queries about this statement. 12 ft. is 1/2 wave at 10 meters (RG 58 and similar). This means that the Voltage or Current will be the same at both ends. The output of a transmitter is 52 ohms (heavy current), the input of the 1/4 wave antenna is 52 ohms (heavy current) so they are matched. This way an antenna tuner is not mandatory. By the way, will anyone with a factory- made magmount base measure the length of the coax supplied ? Is it purely coincidence that 12 ft. is the measurement usually found ? Now if somebody wants to disagree, be my guest , but when you hook up your antenna please check the SWR sooner rather than later !!

I see what you're getting at. I don't think you would get the "same"
results though; the 468 foot vertical monopole would radiate quite a bit
of the energy fed to it, whereas the shorter Tesla coil would not.

Hello Roy,

I have some concerns with your remarks, mainly in
regard to screen voltages, and also I think g1
bias requirements will be different for the 6146.

I realise they were general, but I think they
might be misleading in some circumstances ...
although I'm not sure what you'd consider "minor"
modifications! However, just for some interest ...

Certainly there may not appear to be a "great" difference between the rated g2 max of 250V for 6146 (A&B) and 300V for 807, but I believe the 807 is far more forgiving, and you will see typical operation in the datasheets at the max g2 value of 300 (and of course AF triode operation at 400V) whereas typical operation for 6146 is almost always never more than 200V and often below.

There's an interesting section in the RSGB Radio Amateur Handbook (3rd Ed) that relates to this, in the Single Sideband chapter where a "medium power" class AB2 linear amp is discussed, using a pair of 5B/254M's or 807's in parallel. (the 5B254M is like a miniaturised loctal version of the 807) and modifications are given for use of 6146 in the same circuit, later in the section.

The 807's are running at Va's of either 750, 1000, or 1250V, with Vg2 300, and Vg1's of approx (adjust for specified Ia zero sig) -32, -42, -55V.

Here's the bit I found interesting:
(I denote their single use of *italics* thusly:-)
[p324]

"The circuit of Fig.51 may be adapted to QV06-20s (6146s) by replacing the VR150's in positions V3 and V4 by a VR90 and a VR105 in series to reduce the screen potential to 195V volts. The QV06-20 is far more critical than the 807 or its equivalents as regards screen supply, and a few *moments* operation at normal screen voltage in the absence of anode potential will ruin it irrevocably. Furthermore, the valve should never be controlled by interrupting the screen current and leaving the element floating, because the control grid is liable to suffer damage if drive is applied under such conditions. If it is to be used as a switching electrode in any safety interlock arrangement, the screen should be returned to earth in the OFF position. Unlike the 807, the QV06-20 has been designed expressly for class AB1 operation, and the minimal extra output obtained by driving it into the grid-current region is not worth the effort involved. It is therefore recommended that the meter 0-20mA be replaced by a more sensitive instrument registering 500uA or one milliamp at total deflection, and that it be used to indicate when the stage is being overdriven."

The corresponding table to the 807 / 5B/254M one for the 6146 shows Vg1 -50V for Va 750V, -62V for

Va 1000V, 1250V not recommended. There's a note:

"Care should be taken not to exceed the
dissipation ratings recommended by the
manufacturer. The 6146 is unusually susceptible to
damage through overunning."

Overall, what I find interesting is the remark
that the 6146 is "designed expressly for class AB1
operation" (presumably meaning in linear amp
service, since class C RF and even AB2 AF data is
given for it by RCA, but even so ...) and also
these concerns about the screen grid and so-on.

While the 6146B has a higher Pd than 6146A, the g2
max input seems to be the same (and less than 807)

I note that you can get about as much AF power out
of a pair of 6146 in AB1 as a pair of 807 in AB2.
I'd be *very* careful about Vg2 for 6146 though.

Hopefully some of all that is of interest to some!
(the remark about not leaving the screen floating
relates to an earlier thread in r.a.t. as well)

Regards to all,

Ross Matheson

w_tom wrote:
>
> You have maintained for years that an MOV absorbs all the
> energy of the surge.

You exhibit very limited reading comprehension skills.
I have NEVER stated that an MOV absorbs ALL the surge
energy. I have always stated an MOV absorbs the
surge energy it "sees", within the spec of the MOV.
Perhaps this misunderstanding of yours engenders
your ridiculous and inaccurate posts where you
attempt to state something to the effect of
"according to ehsjr ..."

You are the one that stated in the second post of
this thread on 5/28 at 18:34:
"Surge protectors don't stop or absorb surges.
That is urban myth."

On 5/30, in the 13th post in this thread you
admitted that MOV's DO absorb surge energy:
"Like a wire, the MOV will absorb a minor percentage
of the surge."

But then you go back to your old mantra. In the eight post
of this thread on June 11 you again state: "Surge protectors
don't stop or absorb surges as promoted by urban myths. "

You change again, in the 40th post in this thread on
June 14 when you say: "Like the imperfect short circuit,
the MOV does absorb a minor percentage of energy."

It is your repeated insistence that MOV's do not absorb
surge energy that is inaccurate - and you have demonstrated
that that insistence is inaccurate by your posts, wherein
you claim it, then contradict yourself.

> Are you now conceding that most of the
> energy is shunted and not absorbed by the MOV? Are you now
> conceding that a wire shunts - does not absorb - the surge?
> MOV shunts surges like wire shunts a surge - distributing
> surge energy onto other parts of the circuit instead of
> absorbing energy.

Again, you make me wonder about your reading comprehension.
I stated in the post of mine which you attached:
"In the path, energy passing through the MOV is absorbed in

accordance with ohm's law. It is also absorbed in the hot
wire and the neutral wire and the ground system - all in
accordance with ohm's law. " Where the energy goes is in
accordance with ohms law. Which word did you fail to
understand?

>
> When the first paragraphs has a 120 volt 20 amp circuit
> vaporizing a 20 AWG wire - an absolutely ridiculous absurdity
> - then why bother commenting further.

You are flat out wrong. Reading comprehension again?
The stated case was: "When you drop a #20 wire onto an energized
20 amp household circuit, a small portion of the #20 wire
vaporizes."
You label that an "absolute absurdity".

It was further stated: "The sparks you see when the wire is
first dropped onto the energized circuit demonstrate that.
The burn marks on the wire and the places it touched demonstrate
that. You may even be able to smell the odor, which also
demonstrates that."
What is it about the above that you fail to understand?

> First you must
> acknowledge that a wire, absorbing less than 1% of the energy,
> is not absorbing energy.

Self contradictory statement.

> It is shunting energy to be absorbed
> elsewhere.

Correct. And if you would learn the physics of an
MOV, you would discover that it works by absorbing
energy. It CANNOT go from very high resistance
to very low resistance without absorbing energy.
An MOV works by absorbing energy - that's what
makes it transition to the low resistance state.
In the low resistance state, it conducts massive
current as compared to what it conducts in the high
resistance state. The current flow causes energy to
be absorbed throughout all elements in the circuit
INCLUDING THE MOV, in accordance with ohms law.
The wires conducting the surge heat up. The MOV
heats up. If the surge energy is conducted to ground,
then the grounding electrode conductor, the grounding
electrode and the ground itself all heat up. If the
surge is conducted through appliances, then the path
through the appliance heats up. Energy is absorbed
wherever the current flows.

The MOV and the shunt wire do similar. They both
> absorb trivial amounts of energy while shunting major amounts
> of energy elsewhere. The purpose of an MOV is to shunt - not
> absorb - the surge.

You CANNOT determine what percentage of the
energy is absorbed where without knowing all the
numbers and integrating over time. As another poster
has pointed out to you, the MOV could absorb close
to 100% or close to 0% or someplace in between.
You simply don't know in the absence of numbers.

What you do know is how much energy the MOV is
capable of absorbing - it is rated that way. That
does not mean it *will* absorb (say it's rated at 70
joules) 70 joules - it may not "see" that much
surge energy.

>
> When you insult others

If you want to feel insulted, that's your choice. I have
not intended to insult you. If in fact I did insult you,
then I apologize for the insult. I have described some of
what you have posted as ridiculous or as bizarre logic or
erroneous thinking or things you do not understand etc.
These are my observations of what you have posted, not
personal attacks. I have refrained from your ongoing
snide remarks to me and others concerning EE training.
That said, I will reiterate: if anything I have posted
is in fact an insult, then I apologize. Others enjoy
flame wars, I do not want to participate in them

> AND start every paragraph with words
> such as Bullshit,

If I see it as bullshit, I'll label it as such when I
think appropriate. After several years of this discussion,
it finally became appropriate. Perhaps I erred in this:
it could be that I should have labeled it bullshit long ago.
But once again, you are wrong. You say every paragraph.
There were 22 paragraphs; 5 started out with words such as
bullshit; and it is the first time in our years of posts
you have seen me use that term.

> then clearly your responses are, again, not
> technical

This again calls into question either your reading comprehension
or your motivation. As I've said before, you seem to want
to twist what is said into discrediting someone, rather
than addressing the issue.

> and no longer worth comment.

That is an option you have - feel free to exercise it.
It won't change much - you have rarely commented
on the issues as they were posted and almost never answered
the questions.

>
> The MOV across two lead on a refrigerator motor shunt a
> differential mode surge. Meanwhile, a common mode surge comes
> down one or both AC lines, passes through the refrigerator, to
> find a destructive path into earth.

You stated:
"Even better, short all the AC wires together with wire.
Still the common mode surge will pass by on its way,
destructively, through appliance to earth ground."
That raised the issue:
"Show us the path. We've got the neutral, hot and egc
shorted together at the receptacle into which the
refrigerator is plugged. A common mode surge occurs
and enters your service panel. What is the destructive path
through the fridge to ground?"

What is the path within the refrigerator? What is the
common mode surge? If you want to make yourself clear,
describe what you have in mind when you use the term
common mode. Give us the voltages between each point in
the circuit that you envision so we know what you are
talking about.

> One path may be via the
> linoleum tile or a concrete floor. Or the ice machine water
> pipe. Does not matter which one. If a common mode surge
> finds that alternative, destructive path to earth, then damage
> occurs.

Give us the voltages. Tell us the path. Provide the voltage
drop across each element in the path in the scenario you
envision. What is the amount of current in your scenario
that is destructive?

> The MOV either does nothing because it does not see
> the surge, or shunts the surge over to the other AC wire so
> that a surge has more potentially destructive paths to earth.

Not relevant. The MOV would see equal potential on
its leads with the hot, neutral and egc all shorted
together.

>
> Furthermore there is no reason for a significant surge to be

Right - assuming that by "properly implemented" you mean
the let through voltage will be kept below destructive
levels. But remember, in the real world that can be
damn hard to achieve.

>
> Either way, the MOV does nothing productive.

In the case you presented, with all three wires shorted
together, this is true.

> Stop thinking
> that a differential transient is a common mode transient.

Stop thinking that a common mode transient entering your
service panel will not create a differential mode transient
on the branch neutral and hot wires.

> Until you deal with that basic EE fundamental of common mode
> vs differential mode transients, you will live in a mythical
> world where plug-in surge protectors are effective.

And until you recognize that differential mode transients
exist, you will continue to erroneously think that plug
in surge protectors are not effective.

But if the line is properly matched, the voltage and current will be the
same at both ends *regardless* of length. On a properly-matched line an
antenna tuner is never necessary, regardless of line length.

"Magic" lengths do sometimes help when the line is *not* properly matched;
some line length may exist which will cause the transmitter to see 50 ohms
even when the antenna isn't. Or at least be closer. And at the very least,
using a multiple of 1/2 wave will ensure the line doesn't transform the
mismatch to something that's even harder for the transmitter to deal with.
But if you're matched properly it doesn't matter.

Actually, I think there was a typo in your original post. I'm having a hard
time imagining a PL-259 connector 12 feet long - and I'm getting a headache
trying to figure out how to put it on the cable<grin>!

You should be able to buy them direct from Maxim UK. Details are on the web site. Alternatively, you could scrounge a couple as free samples. Sometimes it's easier to get free samples out of Maxim than it is to buy them from their distributors!

I'm sure Maxim allow a couple of free samples to be ordered via their
website. My employer (Analog Devices) does likewise (www.analog.com)
We have the ADM231 equivalent. For either choice, you will have to
fill in a few details on appropriate website ; if you want a couple of
samples of something else at a later stage, having registered the 1st
time, it will be less of a hassle 2nd time around (with either Maxim
or Analog).

If the input to the antenna is 52 ohms (resistive) and the
characteristic impedance of the coax is 52 ohms, the impedance at the
input of any length of coax conntected to that antenna will be 52 ohms
(resistive). If the impedance of the antenna is anything else, it will
be transformed by the transmission line unless the line is an integral
number of electrical half wavelengths. But in that mismatched case
you're just as likely to need a tuner if you choose one one length of
line as if you choose another.

Thank you for posting this information. I relied on my own experience, which is now about 40 years old, with regard to the success in using a 6146 in place of an 807 a number of times. All my applications were class C, and I believe all simply relied on using a dropping resistor from the B+ to furnish screen voltage, avoiding the problem of having screen voltage applied in the absence of anode voltage.

The information you posted should provide additional guidance to anyone who might want to make the substitution.

All you need is a crystal oscillator, and an RF amp matched to some kind of antenna, perhaps with a low pass filter in there to keep the purity nuts happy, and an audio oscillator to modulate it for ease of use.

If you go to google and type in "foxhunt TX" or something similar you should be greeted with lots of pages of circuits for various ham bands.

Message-ID: <aelpu6$jr6$1@paris.btinternet.com>
Source record: 43291

> Well, please enlighten the group, how did you arrive at that figure?
==========

A half-wave dipole is a tuned circuit.

Like all other tuned circuits it has L, C and R, all considered to be in series.

Antenna Q is calculated in the same way as any other resonant Q.

Q = X / Rr , where X is inductive reactance = 2*Pi*F*L

R is the value of the radiation resistance when uniformly distributed along the wire. In the case of a 1/2-wave dipole it is very simple. It is exactly twice the value which is usually assumed to be lumped at the center.

Rr = 2*73 = 146 ohms which is the same at all frequencies.

Now we have to find the inductance of a straight length of wire, length = 1/2-wavelength = Lambda / 2, and of diameter D.

You can get the inductance from Terman and a dozen other second-hand dealers. They don't always agree with each other.

L = 0.2 * Length * (Logn(4 * Length / D) - 1) microhenries.

Length and diameter in metres.

****

So let's calculate Q of a 1/2-wave dipole at 30 MHz, conductor (rod) diameter = 1/2" = 12.7mm

L = 0.2 * 5 *(Logn(20000 / 12.7) - 1) = 6.36 microhenrys.

Reactance of L at 30 MHz = 1200 ohms.

Q = 1200 / 146 = 8.2

And so the 3dB bandwidth is about 30 / 8.2 = 3.7 MHz.

****

Quite simple isn't it ? Not math - just arithmetic.

However, what everybody forgets, if they ever knew, insofar as the Q of the whole system is concerned, the L and C of the transmission line have just as much effect as L and C of the radiating element. But the transmission line has very little R and so has high Q. So the system bandwidth, as perceived by the user, may be more narrow than calculated above.

Last I heard, Lee Martin lost his aguement that FCC rules governing
sales of amplifiers and amplifier kits should not apply to him. He
learned differently, at least according to QST.

Because his amplifiers never passed FCC TA requirements and were never
issued a TA number, they were pulled from the market.

>of the T coil is a 1/4 wave monopole base fed.

No. By definition, that is incorrect.

A 1/4 wl monopole is, by definition, physically 1/4 wl long.

If the antenna is less than 1/4 wl long, it is properly described by
the physical length. For example, my 160-meter mobile antenna is not a
1/4 wl monopole because it is 12 ft long physically. It is a .02 wl
long monopole.

That would be true no matter how it is loaded.

>blue arc produced at the top of the coil. My point was that I could get the
>same effect with a 468 foot tall vertical monopole worked against ground.

No, you would NOT get the same effect.

The reason you would not get the same effect is because the radiation
resistance of your very short monopole (AKA tesla coil) is very very
low, so very little power is actually radiated as E-M energy. Most of
the applied power becomes heat. Voltage and magnetic flux levels are
very high because the system has essentially no load for the applied
power except the resistive losses of the coil. Voltage and current
have to increase until virtually all of the applied power is "wasted"
heating the coil or making arcs and sparks.

A 1/4 wl antenna would have many hundreds of times the radiation
resistance, and would radiate quite well. Much less end-voltage would
appear on the taller structure, because the system would be able to
couple a large portion of the applied power to space.

If you took the 1/4 wl monopole and placed it inside an RF tight
lossless box, the open end voltage would again become quite high. So
would current.

1/4 wl of wire stretched out as far as possible spatially is a 1/4 wl
antenna. A 1/4 wl of wire or even a full wl of wire in a 1/100th wl
area is a 1/100th wl antenna, nothing more.

They are nothing alike.

Good question. The 982 has a 1.2 dB noise figure. I see the 961 has a 1 dB noise figure. I don't know if the max Id reduction would be an issue or not. I saw that the BF982 was recommended as a replacement in the front end of the Yaesu FT-726 to reduce noise and increase gain. I thought I'd give it a try, but they sure are hard to come by.

>before it vaporized. :)

Maybe, but maybe not.

Think about it.

We have no idea what the energy level was. While we might assume
total system energy was considerably higher than the energy required
to vaporize the wire, we have no idea if that is true or not.

We don't know anything about the rest of the system, it could have an
ESR of nearly zero ohms, or a million ohms. We only know the wire
consumed enough energy to vaporize, and that might have been near zero
percent of the system surge or near 100%.

Now the real question, how can there be a 300 line argument where one
person calls the other a dummy....when no one could possibly know the
distribution of energy in the system?

Wait a minute Doug.

If the line is 50 ohms, and the load is mismatched, there is NO length
of 50-ohm line that will cause the impedance to be a better match to
50 ohms. SWR remains the same all along the line, so mismatch is the
same all along the line.

It is a circle on a Smith Chart, and never ever gets closer to the 50
ohm j0 center.

The only exception is if the line has significant loss, and then the
longer the line the better the match.

Sorry John, but that is not true. If the load is 50-ohms, the line has
the same voltage and current all along its length.

If the 50-ohm line is mismatched, and you have it grounded correctly
at the antenna, SWR and match does NOT change with line length.

If you are finding it to change, you have something wrong with the
grounding, the feedline, or the meter you are using.

Hi Fellas;
I have for SALE:
Many small bags with various qty's of NOS micas, etc!
If you see anything you can use, e-mail me & i'll give you more info. This will save me time if no one is interested!
Sangamo red mica caps, 74pf, 3740pf, 150pf, 450pf, 4170pf, 27pf, 50pf, 74pf, 400pf.

El-Menco red micas, 300pf, 12pf, 500.510pf,

Samgamo dipped micas, 1450pf, 732pf, 68pf, 150pf,

Bag of 1" lg approx. 10mhy ww RF chokes.

Bag of .02 Sprague Round axial caps.

Thanks es 73....Rich WA2RQY (1961)

> helpful.

2 KM range, huh ?

Well, 2 meters can do that. Besides most hams will have 2 meter radios
so it is probably the best band to use for a club T-hunt.

You will of course have to use a 5/8 wave antenna or some such on the
transmitter. It will also need a big enough battery to provide power.
This all makes the unit relatively large.....

==========

You will need a transmitter and an identifier as well to be legal. Any
other sort of unit will probably have a LOT of people employing RDF to find
the illegal Tx.

I seem to remember that Ramsey Kits has some type of kit that is a
"hidden" transmitter for RDF hunts.

Alternatively, there is a book about transmitter hunting that most ham
radio stores will have which shows construction information. I am sorry
to say I do not recall the precise title, but it is a fairly well known
book.

Many RDF hunts use a ham with a mobile as the fox and that works nicely
for a hunt that is meant to be over a large geographic area. A regular 2
meter mobile setup has enough power and the operator will identify often
enough to satisfy the FCC.

Source record: 43153

A quick EZNEC calculation of a 1/2" diameter resonant dipole at 30 MHz shows the Q to be 6.82 (equivalent feedpoint L = 2.60 uH). The L is easily determined by having EZNEC calculate source impedance at two frequencies, one just above and one just below resonance. I used 29.9 and 30.1 MHz. Call the difference between the feedpoint reactances at the two frequencies DX (6.536 ohms in this case) and the difference between the two frequencies DF (0.2 X 10^6). Then L = DX / (4 * pi * DF) = 2.60 uH for this antenna. (This formula for equivalent L is valid only near half wave resonance.) The reactance of a 2.60 uH inductor at 30 MHz = 490 ohms. Divide this by the feedpoint resistance at resonance reported by EZNEC (71.9 ohms) to get the Q of 6.82. Reg's simple calculation of gives a result (Q of 8.2) about 20% high, not too bad for a simple approximation.

I repeated the experiment with a 1/4" diameter dipole, and got a Q of 9.11 using Reg's method and 7.75 using EZNEC. Calculation using Reg's method are only 18% higher in this case, so the accuracy of that method apparently improves as the wire gets thinner.

Modeling an antenna as a series RLC network is valid only near odd half wave resonances (and the values of R, L, and C are different for each resonance).

542. 6LB6 in FT-101

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-18 14:57:41 UTC
From: "Scott M." <scottzm@netzcommander.com>
Message-ID: <3d0f486a_6@corp-goliath.newsgroups.com>
Source record: 43155

Does anyone have any experience using 6JB6s in the FT-101 in place of the 6JS6s? If so, what changes do you need to make? Neutralization cap? Are they as good as the 6JS6? All comments welcome.

Thanks,
Scott M.

543. Re: How to make a 10 Meter mobile antenna?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-18 15:03:07 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aeni3a$op7$1@helle.btinternet.com>
Source record: 43156

An interesting comparison between Roy's Eznec inductance and Terman. A discrepancy of 20%. This seems high so I took another look at Terman.

Terman's inductance formula is for a straight length of wire. He does make corrections for the difference between VLF and HF values. But he makes no mention of wire lengths which are an appreciable fraction of a wavelength. There's no reason why he should. He is more interested in the practical values of inductance of connecting wires between radio parts and components rather than antennas.

When a conductor is longer than, say, 1/10th wavelength the current may no longer be uniform along its length. When examined in the context of inductive energy storage the equivalent uniformly-distributed inductance is a little less than when the current is uniformly distributed.

Another way of looking at a 1/2-wave dipole is to consider it to be two 1/4-wave 'verticals' connected back-to-back. If the inductance is calculated for each 1/4-wave seperately and then added together we find the total inductance to be less than that of just one length of wire.

So a more accurate formula (but just as simple) for the distributed inductance of a 1/2-wave dipole is -

L = 0.2 * Length * (Logn(Lambda / Dia) - 1) microhenrys.

Using the previous example: F = 30 MHz, Diameter = 1/2" the inductance is 5.44 microhenrys. Note that the length is the truly resonant dipole ngth - that which has been pruned (by about 4%) to give zero feedpoint reactance.

The discrepancy between the above formula and Roy+Eznec is 4.6%. Which is more than good enough for the purpose intended.

I would guess that Roy's hazardous method of determining dipole inductance is just as likely to be the reason as inacuracy in the formula.

Incidentally, in my programs where dipole inductance is involved in an analysis the above formula is used. But the value of antenna inductance is not reported in the output data. It is seldom of any interest.

Even assuming that this is any sort of a good idea; it will only be true
at one specific frequency. Since 10M is a pretty wide band it will be a
long way from a 1/2 wave as you tune away from the frequency it is cut
for - or did you plan to limit operation to a single frequency?

Just check the SWR at various points on the band and this becomes
immediately obvious.

Well Pete'e

You imply that 4cx250b type tubes are bad news in the IMD department.
There are many tubes with better operational IMD specs, but the 4cx250b
family works just fine in linear service. IMD is not any type of problem
if you pay attention to the proper circuit and operational details. Basic
linear amplifier 101 related to a specific family of high gain tetrodes.

If any of the 4cx250b family of tubes are around cheap/free, one should
not be scared off from using said by people posting blanket bad news IMD
statements on New Groups. How about you posting some comparisons of IMD
operational preformanc of some popular tetrodes vs the 4cx250b family and
we'll beat the data back and forth.

The 4cx250b family of tubes work well in properly designed and
constructed linear circuits, simple enough.

Your turn to "enlighten us" with some actual data that you have measured,
not something reprinted or quoted out of an older Handbook...

thats pure garbage. 10db is still 10db regardless of what band or the shape its in. a 25 watt radio with a mobile antenna doesnt come close to the signal of a 100 watt rig and a dipole does but a 250 watt mobile with a qaurter wave whip isnt too shabby and wont be at a disadavantage when compared to a fixed station. the original poster would just be best off buying either a texas star 400 that runs a qaud set of 2sc2290's or a texas star that runs a dual set of 2sc2879's. either one of these boxes will work fine and are used by many hams world wide for mobile dx'ing.

Last I looked at Lee's website (around a month ago) he stated he was
back in business!

I have a local RF designer here in London laying out a single board with
16 of the 2SC2879's on it just to see if it can be tweaked to see that
magic 1500w peak (after filtering) from a stock 100w HF transceiver as
the driver on a stiff 14v rail into a big Bird Termaline.

The data sheet says no, (lack of enough drive) but I'm a perpetual
optimist.

I just ordered this RDS/RBDS radio card. So, I'm going to be trying
out different programs from the 'net for using/decoding those signals.
Please let me know your experiences and if you have any programs or
hardware for using the RDS/RBDS signals from this card. It only cost
$6.50 for this radio, apparently heavily discounted for whatever
reason I don't know. But for that price it should be worth it.

Again, any information, advice, additional hardware, cables or
programs for this ISA card would be much appreciated. Here are links

Uh huh, so 100 metres later it may have spiralled down towards an
acceptable match? Not very practical, unless you want a dummy load.

Resonant feedlines are only useful for repeating the load impedance for
measuring purposes or for current forcing in arrays. To effect any kind
of match you need stubs or a chunk of different Z line.

The BF961, BF981, 3SK88 and 3SK45(tin-can) are all very
good on 2M. I have two rigs for 2M. One has a BF961 in
the front-end, the other has a twenty year old 3SK45.
Both rigs are good enough to hear GB3VHF (603KM away) even
when tropo' conditions are poor.

>A 1/4 wl monopole is, by definition, physically 1/4 wl long.
Hi Tom,
Ok, by definition I stand corrected.

>If the antenna is less than 1/4 wl long, it is properly described by
>the physical length. For example, my 160-meter mobile antenna is not a
>1/4 wl monopole because it is 12 ft long physically. It is a .02 wl
>long monopole.

Yes, but my 160m mobile rig thinks it has a 1/4 wave vertical out there because
of all the loading and matching I have to do.
.>>blue arc produced at the top of the coil. My point
was that I could get the
>>same effect with a 468 foot tall vertical monopole worked against ground.
>
>No, you would NOT get the same effect.

The point I am trying to make is that a 1/4 wave monopole and a Tesla coil are
both resonant. You can make a 3' coil and a 468 foot vertical both resonant at
the same frequency. They have a current maximum at the base, and a voltage
maximum at the other end. Other than that, no similarity. A T coil is not a
good antenna, 1/4 wave monopole is not a good T coil. The first response to
the orginal poster was refering to helical wound cb mobile antennas acting like
Tesla coils at high (transmitter) power. I was stumbling around trying to
explain why.
BTW I did get enough rf from my T coil to open my garage door. Arc, induction
field, or actual radiation from the coil?

You missed the point, Alan. Tom stated:
"If the line is 50 ohms, and the load is mismatched, there is NO
length of 50-ohm line that will cause the impedance to be a better
match to 50 ohms.". That is ONLY true of a lossless line, and in my
thirty-plus years in the industry I have yet to see one.

And as an aside, yes we have used trickie dickie's cheap "RG58" as a
dummy load at UHF, unterminated at that ...

What on earth do you want these for? I was playing about with them 25 years
ago, and they aren't much use for current designs. I don't have any, BTW.

>world wide for mobile dx'ing.

I would certainly hope NOT.

There is a danger in purchasing totally illegal non-type-accepted
amplifiers, like the illegal CB amplfiers manufactured by Texas Star.

They operate class C, and have poor or no filtering. That means they
splatter and trash up the ten meter band, and will even cause TVI and
you might also run the risk of interfering with other licensed
services. In fairness, they would be suitable for FM and CW use if you
added a low-pass filter.

I've actually measured some Texas Star amplifiers, and they were in
the area of -15dB IM3 below one tone, and had harmonics suppressed
only 20 dB!

To put it bluntly they belong only on the CB band with illegal
operators, not on the amateur bands! Ten meters is bad enough with CB
QRM, we don't need a bunch of hams trashing the band with CB amps.

No, your radio simply "sees" a low SWR load. It does not see a "1/4 wl
antenna" unless there is one.

>The point I am trying to make is that a 1/4 wave monopole and a Tesla coil are

True enough, but we have to remember the limits. A coil generally has
very close to uniform current throughout the structure. A large
monopole antenna does not. That mostly has to do with the EM
radiation.

The exception is if the coil radiates a significant portion of the
applied energy, like the antenna does. The exception requires the coil
to be physically large in terms of the wavelength, or has significant
current shunting loads along it's length.

>thirty-plus years in the industry I have yet to see one.

You are intentionally or unintenitionally misquoting me by lifting
only PART of what I said from my post.

If you include the last sentence, you will see I already cover the
real-world lines. I said:

"The only exception is if the line has significant loss, and then the
longer the line the better the match."

The key word is **significant** loss. For ANY line to improve the VSWR
through length, when line impedance equals desired system impedance
(like a 50-ohm load in a 50-ohm line) the loss MUST be significant.

The loss is generally **NOT** significant in twelve feet of coax on
ten meters, so the SWR reduction he claims can not come from line
length with the exception that his meter might not be calibrated to
the line Z0 or the system might have common mode currents that are
changing the load impedance seen by the line as line length is varied.

There is enough misunderstanding about this without complicating the
discussion by misquoting people.

I joined this thread lately and have probably missed significant portions, but Tom is right. In fact, if the vertical conducting structure gets to be short enough, then you essentially end up with a helical whip. For 160 mtrs, these pitches would probably yield an antenna efficiency of -30 dbi at best, but this is a stab in the dark for value. Put another way, it won't be very efficient. If practical (I don't do 160), a loop would be better for 160.

BTW, what happened to the thread about 10 MTR's? An 11 MTR bumper mount works great when pruned. Don't get concerned about line loss in the RG58. It's not much at these freq's. Also, please don't flame me because the whip is at 38 ohms or thereabouts instead of the 50 ohms of the RG58, mismatch loss is not that bad either.

Salut Jos.

If you don't have any luck finding a commercial one, there was a
RLB designed by Paul Wade published in QEX that goes up to 2.4 GHz.
It will measure both 50 and 75 ohms, depending on how it's set up.

I still beg to differ. ANY loss will improve the match. Significant
loss will introduce a significant improvement.

>There is enough misunderstanding about this without complicating the
>discussion by misquoting people.

You made the statements. Either alone is incorrect. Both together
remain incorrect. There was no misquoting whatsoever, and I do not
believe that either part was taken out of context. YMMV as much as you
like.

Cheaper and quicker shipping is one reason that many US/Cdn would
prefer a source in the US or Canada I suspect.

Of course paying a high prices for BF9xx in US doesn't make sense if
you can get them at a reasonable price in another country.

I'd like to ask, have you ever had problems with foreign (not incld.
US) electronics by mail order? E.g. Customs, shipping, currency
exchange rate, etc.

Sidenote: I'm trying to find about a dozen MB506 Fujitsu 2.4 GHz
prescalers, which appears to be obsolete now. I'd prefer DIP but would
consider the SMT version as well. Any advice?

Thanks. VE????

Scott,

If the replacement tube would cause you to rewire the socket (which might require screen and bias potential changes), would it be worth the bother. Based on the prices I see for used 6JS6 vs the 6JB6, I would stick with NOS 6JS6 tubes. Yep, the neutralization cap value would need to be tweaked, but even a change to same type replacement tubes should require the Neutralization cap to be checked/set.

If you can retro a replacement similar tube into a tranceiver because of high NOS tube costs or short/unavailable supply... ok if its worth the work.

cheers

I believe that when you offer a quote, the quote should stand alone
(be its own paragraph) and not have one of your comments tacked on the
end as you did when "quoting" Tom.

Had Tom's statement stood alone, there would have been less chance for
the misunderstanding that seems to have taken place here.

As I recall, it's a bit complicated. You get the part number from wherever,
I had them from the schematic, and them email to Robin telling him what you
want and does he have them. Probably not the most straightforward procedure,
but it's better than not being able to get them at all over here.

430's have a "known failure mode" for the final output transistors. This is a combination of a circuit board that is a little to light duty and riveted transistor connections. I have fixed 2 of these, and one acted very much like yours with a pll / vfo "unlock".

588. permeability problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-19 20:01:32 UTC
From: dstalk@exculink.com
Message-ID: <wq5Q8.27496$Z6.317334@nnrp1.uunet.ca>
Source record: 43099

Hello,

Perhaps some of the more enlightened hams can explain to me what I'm
doing wrong when I try to determine the permeability of a ferrite rod.

I wanted to build a Tuna Tin 2 using some ferrite rods that I
already have. This led me to look at the Radio Shack 273-101
which was used in the original rig.

The 273-101 specifications are:

inductance: 10 uH
number of turns: 31 [1]
rod diameter: 0.25" [2]
rod length: 1"
coil length: 0.67"

When I calculate [3] the the "open air" inductance of the coil,
I get 1.9 uH.

Now, my understanding [4] is that the permeability of the rod is:

L(with core)/L(open air) = 10/1.9 = 5.26

My problem is is that, in the original Tuna-Tin 2 article [5],
Doug DeMaw states that the permeability of the rod material
is about 125. That's quite a bit different than my calculations.
I understand that the "rod" permeability and the material permeability
are not necessarily the same [6], but for a rod of this dimension they
should be quite close.

Can someone show me where I've gone wrong?

Thanks and 73,

Don ve3hur

=========
Unless of course a Ham with homebrew experience converts such an amp for
linear operation
in class AB1 ,be it (possibly) with a somewhat lower RF output.
It might even be possible to convert such a unit to a decent 50 MHz linear
amplifier.

Source record: 43102

Mike,

I believe that you are correct. The value of the effective shunt resistance would be 447 ohms. In this case, the insertion loss would become 6.4 dB. Or maybe Mr. Bowick meant that the Q of the coil was 100 instead of the stated 10. This would put his 4.5K resistor in the ball park.

You could build one?

If all you want is a fairly stable signal for tuning up IFs, just build a FET oscillator, add a buffer, a low impedance driver, and a POT for a level adjustment. Then make yourself up some 50<->50 pads for whatever attenuation you want, say 3dB, 6dB, 10dB, and a few 30dB, or a switchable attenuator. Should cost < $20, perhaps the variable cap for the oscillator being the most expensive part.

You can also rig up crystal oscillators for various IFs if you want spot frequencies with accuracy and stability. A frequency counter or receiver is all you need for absolute frequency alignment with a sufficiently stable oscillator.

You'd need a scope or RF volt meter of sufficient bandwidth to get accurate level calibration for sensivity testing, or take the finished product to a mate with the equipment to calibrate it and the attenuators.

You can also buy some cheap and nasty RF signal generators for < $50 new, and there is always the second hand market. They are all basically just oscillators with a buffer, the only bells are PLL locking, digital read out, calibrated output, inbuilt step attenuators, and sweep/tracking ability, which is probably all overkill anyway.

A simple oscillator would (I think) be too unstable for narrow receiver
use.
I would suggest crystal oscillators for a few selected frequencies.

Also stray radiation from the circuitry will be a problem for weak
signal testing.

My recommendation; put one or more crystal oscillators in a sealed box.

filter the power leads. and remove the signal using a "wave guide beyond
cutoff"
variable attenuator. The attenuate uses two coupling loops inside a
brass tube
with the spacing of the loops adjustable.

Details of this construction should be available on the net someplace.

Alan's suggestion was pretty similar to mine but a lot less specific.

In a recent QQ there was an article on building an attenuator, might have run over a few issues. Find someone local who is an ARCI member and hangs on to those things. It's actually pretty tough to get a signal down low enough that it can be useful for testing modern QRP receivers (even simple homebrew ones). You're not going to find an inexpensive signal generator that can do that.

This sort of attenuator isn't all that simple a project, but the parts count is small so it's not too expensive. It's just a ton of work.

Alan's crystal oscillator idea was good, I would find some NJQRP Fireball-40's. NJQRP hawked a million of those things, and although they no longer sell them, there must be a lot of them out there, unused or unbuilt. I'd suggest posting QRP-L and see who has one to sell. These things were ten bucks new. You probably want a few.

If you get to wanting to build a crystal oscillator or five, look into the Epson SG-8000 series of package oscillators from DigiKey. These things sometimes have quite a bit of phase noise, so they aren't great for local oscillators, but they are just fine for testing, and at $3.33 each, they won't break the bank. Plus, if you find some FB-40's, you can plug 'em right in and avoid any work at all. Just be sure to specify UPS Ground - DigiKey's standard shipping is second day air and the shipping will cost you ten times what the oscillators cost.

Source record: 43108

The effective permeability of a coil wound on a rod is much less than the permeability of the material the rod is made from. That's because there's a long air gap in the magnetic path (from one end of the rod to the other). This long air gap has a relative permeability of 1, and it appears in series with the magnetic circuit. The relationship between the effective permeability and the rod material's permeability depends on the length/diameter ratio of the rod and the rod's permeability. Only when the magnetic path is entirely in the material, such as a toroid or ungapped pot or EI core, is the inductor's effective permeability the same as the material's permeability.

There's a funny thing about ferrite rod antennas of the usual dimensions.

Regardless of the actual permeability of the rod material, the EFFECTIVE permeabilty of the rod is usually in the vicinity of 20 to 25. With a bundle of rods, containing air gaps, it will fall in the ratio of air-to-ferrite cross-section.

This is because much of the magnetic path is in the air gap between the ends of the rod. (Like a bar maget). When the rod permeability increases above 100 or so, the effective permeabilty doesn't increase much more.

The effective permeability is determined by measuring the coil inductance twice. Once with the rod inserted and again with the rod removed. Mu = L1 divided by L2. You can then calculate the number of turns to put you in the desired frequency band. Twice the number of turns will halve the frequency with the same value tuning capacitor. And that's about all you need to know.

There is little point in using material permeabilities greater than 200. This is a nice value to stop at because this is the value at which ferrites have the lowest loss, ie., give the greatest coil Q up to roughly 2 or 3 MHz. At higher frequencies you will be better off using some other sort of antenna.

Far and away the best way of designing a rod antenna is to obtain a rod which will fit inside your equipment, the bigger the better, wind some turns on it and see what you get.

The efficiency as an intenna is invariably terrible. It is worse than a 3-feet whip antenna. But at least you can get it inside the pocket receiver case and it is easily Z-matched to the first transistor. Which is the only reason the cussed things are ever used.

Please don't take a pessimistic view. You can have great fun experimenting with very few and inexpensive materials on the kitchen table. Believe me, that's the way the top designers do it !

Ph.D's have produced 'learned' but useless papers on the subject. Well, everybody tries to make a living of some sort.

Ain't that the truth. I started to build one of those switchable jobs,
with each stage shielded carefully. It took hours per stage, and the
switches bled through too much in the end.

Now days I just build discrete attenuators with inline sockets.

Bleeding around the things and coupling via the power supply of the
signal generator limits the lower limits of testing. If you are just
tuning for best sensivity you can move the generator away, or stick it
in the fridge or something.

Actual measurement needs calibration and lots of effort for accurate
results. I've never bothered to go that far, so within 6dB is OK for
me.

> Alan's crystal oscillator idea was good, I would find some NJQRP

I've built a small single transistor test oscillator, just a
fundamental, no overtone tuned circuits, with a crystal socket and a
battery all inside a cast Al box, the only thing sticking out is the
BNC, the power switch is simply plugging in the battery snap.
Unfortunately it needs to be calibrated for each crystal's output level,
but it is scaresly detectable with the ouput shunted with a dummy load.

Doubles as a crystal checker.

I guess you could stick the whole thing with the attenuators into
pieces of pipe if you wanted to be really sure there was minimal
feed-around, but I've never found that to be a big problem, maybe my
receivers are just deaf :-)

My VFO signal generator is similar, all in the one metal box with just
the RF socket, power switch, pot and tuning cap spindles sticking out.
The coils are socketed on DIN plugs inside, and the power is from a 9v
battery.

Check out the transmitter on a chip from Micrel at http://www.micrel.com.

The transmitter is for On/Off keying but you could hold the carrier and frequency deviate the reference crystal to product narrow-band FM modulation.

If you design around 433.92 which is another common frequency, the ref crystal, which would have a freq of 433.92 divided by 32 (MHz). These are easy to obtain, I am not sure about 418 MHz ref crystal.

Another method is to use a colpitt type osc circuit and varactor diode to create FM modulation. This is a much harder method where as the transmitter on a chip is easier to get going.

Micrel has a PCB demo board you could start with.

Cheers,

Good Luck

I agree with the comment that these are pretty old to be used in
a new design; they are over thirty years old. If you just need
the function, the CD4046 has the same sort of phase detector in it,
and uses less power. The VCO would be about the same as the 4024,
though the frequency range is much less. The 74HC4046 might get up
to about where the MC4044/MC4024 combination topped off at. Or,
there are other possibilities, and you really need to be less vague
about what you need these for.

If you are talking replacement, I've seen the pair in old floppy
disk controllers (I guess they were used in the data separators);
I can't remember if it was the controller for the PC jr, or
just an old controller for the "IBM PC".

Funny, I understood Tom's post. All of his statements
are correct. It is clear he is talking about a lossless
line in the first paragraph - you even mention it. And
it is equally clear that he is talking real world in his
last paragraph where he mentions the coax with significant loss.

A statement addressing the principle of impedance transformation
via lossless line such as Tom's is not refuted by a statement
that requires lines with loss.

Nor does a statement that ANY line has loss, such as yours,
refute the statement that to get a "better match" you need a
line with significant loss.

I think the only question here is concerning how much
loss and how many feet make a real world difference, so
I'll ask you what you have in mind: how much additional coax,
at what loss per foot, would have to be added to the 12 foot
length to make a noticeably "better match"?

When
discussing impedance transformation created by a length
of coax with someone who apparently does not understand
what goes on, you need to establish that there isn't any
with a perfect, lossless match. Only then can you make
it clear that

Hi
I've been playing with remote operation of the Philips
1000 series synth but it uses a Two-Modulus system
of which I know very little, I gather its a way
of increasing the resolution of the synth to a few
Htz but presumably not used to it full extent for
just 12.5khz spacing in the 1100
Can anyone give me an idea or an example how to
work out the data for standard 12.5khz operation
I understand how to load the data into the R counter
A counter and M counter but a bit dim on the operation
of the control logic. also is there a way of ignoring
the 2nd Modulus? ie just run it as a standard Single
modulus system? any information welcome
The synth chip is a NJ8821 with an SP8703 divider
and a ref xtal of 8.4mhz for the 2mtr band.

from Ron g3yuh....

>amplifier.

Hi Frank,

Even if we would add a stiff positive bias source and move the
collector conduction angle to class AB (there is no AB1 or AB2,
because it is a transistor), and add a filter, we must run a CB amp
like a Texas Star at a fraction of the manufacturer's published power
to maintain any type of reasonable linearity and IMD performace.

Of course on FM, andto a large extent on CW, that isn't a problem
because linearity doesn't matter, so they are OK amps for those modes
(if filtered to reduce harmonics).

You'd also have to educate the user to not use the amp anywher near
rated output on SSB. Most CB amplifiers, including the Texas Star, are
rated at or even far beyond the saturated power output level of the
transistors.

A typical 100W CB amp will only run about 20-40 watts of reasonably
clean SSB peak power, after you change the bias and add a low pass
filter.

As in a radio, you need a LOT of headroom on a solid state PA to keep
it reasonably clean.

As long as we are picking nits, that is not true. Increased loss in a
transmission line can also make the apparent line SWR worse.

On the other hand, a significant change in loss might not make a
noticable change in SWR.

But then I'm sure you know that, and just didn't say it right. ;-)

Then what's your gripe?

The statement that I took issue with related to length of line and
possible improvement in match. And to reference the REAL world where
lines do have loss doesn't smack of idealism - rather it relates to
the O/P's question as much as rotation on a Smith Chart.

>Nor does a statement that ANY line has loss, such as yours,
>refute the statement that to get a "better match" you need a
>line with significant loss.

Whoa big boy! I repeat, and I'll try to use small words so you can
keep up: ANY loss will improve the match. ANY loss will give a
"better match". And anyone who can work out an R.L. can see how much
loss they need to get a certain improvement if the source end is
matched.

>I think the only question here is concerning how much
>loss and how many feet make a real world difference,

AHA! We have a breakthrough!
>so
>I'll ask you what you have in mind: how much additional coax,

(Dunno where that bit belongs ....)

You can't change the laws of physics just because your audience may not understand them. If having that audience sector keep up is so important, that situation calls for a bit more effort to EXPLAIN them.

Tom's first statement I reiterate that ANY loss improves the match. You now introduce the concept of a 'noticeably "better match"' which is a different story entirely.

As Roy has said, the effective ueff of a rod is much less than the rod permeability urod.

There is a useful graph of Ueff versus L/D ratio and urod in the FairRite catalog:

http://www.fair-rite.com/fr_catalog-14thed_rev3.pdf

Jump down to Page 131 of the catalog for the graph.

In your case, L/D = 4 and urod = 125 (Type 61 material from FairRite). The graph shows ueff = 12.

While ueff doesn't match your measured ueff of 5.26, it's a lot closer than basing the calculation on urod = 125.

In truth, there are several more corrections that must be applied:

*Ratio of coil length to rod length
* Coil offset from being centered on the rod
* Winding "fill ratio" tied to the ratio of "copper" to open air in the coil.

I spent an interesting few months a couple years ago trying to understand these factors and wrote about 90% of an article attempting to describe in a quantative fashion all of these various factors with respect to ferrite rod antennas. If you are really interested, I'll e-mail you a copy. It's not finished, and is several Mb long, as it has embedded graphs and photographs. Microsoft word format.

Hi Group,

Having problems getting a series T-10 relays. Can not even find them on the
web.
Anyone have one with a 5V coil?

Paul

To make meaningful sensitivity measurements you need *very* good screening
on the signal source, and the leads (double-screened are best), especially
with a sensitive Rx.

I had a great deal of trouble once with leakage when I had to demonstrate to
the customer that a pair of military HF transceivers could operate
effectively in various modes at the lowest specified signal level. I had to
use two screened rooms connected by a double-screened cable.

I'd do as several people have suggested, a crystal oscillator in a shielded box. You can power it either with CAREFULLY filtered and bypassed wires or possibly a built in battery.

As for a way to set the level, I'd build in switched attenuators using slide switches and resistors as shown in ARRL handbook.

Be careful to keep the maximum attenuation per switch section to 20 dB. There'd be too much signal leakage around the switch if you tried for more attenuation in a single switch.

I have built several of these attenuators over the years, using regular 10% resistors and they have been accurate to 1 or 2 dB up to about 500 MHz. The top frequency limit depends on precise construction technique, but for up to 100 MHz you can expect good performance. Just keep the wires short and use shield walls everywhere to force the signal through the switches.

Build the entire thing, including the attenuators, in a shielded box using copper clad printed circuit board.

And, of course, shields between each switch section. The ARRL handbook shows a good construction technique.

You can easily get enough attenuation and it you power the oscillator by a built in battery you remove the most likely source of signal leakage out of the oscillator.

This should do what you need, and I suppose you could add a switch to switch a couple of oscillators for different frequencies in the same signal generator.

Hi

Can you help me to find the schematic of a simple but effective ssb receiver.

It will be tune over a narrow band around 13.5 Mhz with a VCO of my own (DDS).

There is a single chip solution; is the direct conversion the best way to go ?

Any help or suggestion will be appreciated.

Thanks in advance for you collaboration and excuse my English

I'm not aware of any single chip solutions for such things. You basically have two choices: direct conversion or filter. They each have advantages and disadvantages.

If you're really not concerned with selectivity, you can buy a narrow ceramic filter or build a two pole crystal filter which should do reasonably well. Build your receiver around a couple of '602 chips and a 386 audio amplifier and you've built a pretty good beginner's radio.

If you're looking for performance and just slightly more complex circuitry, I'd like to recommend KK7B's R2 series of receivers. In particular, the miniR2 would meet your needs very nicely. Dynamic range is very good, audio quality is excellent, and opposite sideband rejection can approach 50 dB, given a reasonable effort at matching parts.

The down side of the miniR2 is that you'll need higher power than typical coming out of your DDS to drive the two mixers. Most builders use +7 dBm LO drive for the mixers, meaning you'll need at least +10 dB coming out of the DDS buffer amplifier, unless you have both I and Q outputs already.

If you're interested in the R2 series of radios see

http://www.bright.net/~kanga/kanga/kk7b.htm

Good Luck!

621. new program - feedline radiation

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-20 21:34:47 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aethpm$5mi$3@paris.btinternet.com>
Source record: 43134

New Program FEEDPOWR.exe

RADIATION FROM BRAID OF COAXIAL FEEDLINE.

Radiation due to unbalanced feedline currents is often considered undesirable.
It may sometimes be thought useful. The main effect is distortion of the radia-
tion pattern. Power loss in a wanted direction can occur - but how unfortunate
is it? Signals or noise from an unwanted direction can be a nuisance - but how
much of a nuisance? An estimate of the strength of feedline radiation before
taking precautions seems desirable. Precautions might not be necessary

A crude estimate will be sufficient because much of a feedline''s length runs in
a cluttered, uncertain environment. This program models and analyses the most
simple and worst-case situation - a dipole centre-fed via a coaxial line.

An RF source is placed at the centre of a horizontal dipole of given length and
height. Also from one side of the source a 3rd conductor descends to ground
level where it is grounded via a loss resistor. This 3rd conductor corresponds
to the braid of the coaxial feedline from the antenna back to the transmitter.

The 3 radiation resistances are computed. Then input Z of each of the 3 conduc-
tors followed by the 3 input currents. Finally the percentage of radiated power
contributed by each of the 3 conductors is calculated.

A balanced-to-unbalanced transformer (balun) at the antenna end of the line can
constrain the currents in the conductors to be equal and opposite to each other.
Line radiation is then reduced to a low level and the radiation pattern remains
undistorted. This program does not allow for currents being re-introduced in the
line due to the line not being led away from the antenna at a 90 degree angle.

The need for a balun with a simple dipole is much debated amongst radio
hams.
Attention is focussed on feedline radiation and on a line''s receiving
ability.
But with only anecdotal evidence offered by participants debates inevitably
fail
to arrive at any conclusions.

In the absence of numerical information on the subject this program attempts
to
fill the gap. There is only one quantity of consequence - the fraction of
total
power which is due to unbalanced feedline current. It depends only on
antenna
dimensions and frequency. That radiation emanates from any particular part
of a
structure is a popular misconception but in this case the myth serves a
useful
purpose. The analysis involves some simplifying assumptions justifiable on
the
grounds that the uncertainties introduced are probably no greater than the
un-
certainties associated with details omitted from the input data.

As will be seen, radiation from a coaxial feedline in a particular
installation
can vary widely with frequency. Random resonances occur. If by some chance
one
occurs in an amateur band it can be shifted by changing the feedline length.

From: Kurt Stocklmeir <kurtstocklmeir@worldnet.att.net>
Message-ID: <01c2189a$5f26be40$3e755b0c@oemcomputer>
Source record: 43135

I think people say some thing like when an electromagnetic wave hits a conductor the electric field is suppose to not have an intensity. This can be compared to standing waves on a string between 2 ends. I think people say there are only standing waves between 2 conductors. I do not know how a photon gets absorbed or reflected when there is not any electric field intensity.

A lot of times a photon which is an electromagnetic wave hits a conductor and the electric field intensity is big. I guess the electric field will be absorbed by the conductor
and electrons will start moving. It is probably true the electric field will be destroyed fast and it will not travel a lot pass the surface. I guess if this is true there can be waves between 2 conductors that are not standing waves.

Thank your for any answers.

Extender boards are often used in troubleshooting live equipment, when
you need to measure or adjust something on a board normally in a card
rack. Your design is quite similar to the ones I've worked with.

Pay attention to not zapping yourself, or shorting something on the
board as you do this. Use test leads with insulation except for the
very tips. If there is any serious voltage, use the one hand in pocket
rule.

You might have odd RF issues because the case would not be closed up.

Happy trails,

Hi Hams,

Looking for a 100 MHz series-resonate crystal for a mixer project out of Ham Radio Oct '95. It has to operate on the fundimental mode.

Mostly see crystals up to 50 MHz but no 100 MHz.

So, if anyone has a source or suggested source let me know.

tnx de KJ4UO

(much snipped above)

The thread talks about a reduction in SWR.
The threshold of noticeability would be a
distinct difference in the swr reading using
a vswr meter before adding the cable and after
adding the cable. I would think a "noticeably
better match", in the context of this thread,
would be bringing the VSWR say .5 closer to 2.0
from somewhere near 3.0 So, in your view, how
much additional coax, at what loss per foot do
you have in mind?

Hamfests. Look for old boatanchor signal generators.
I bought a beautiful Boonton generator for $15.00

The thing has a beautiful variable attenuator to
-125 Db, covers Audio and all of HF and produces
a beautiful and stable sine wave.

Draw backs: large, heavy and you have to let them
warm up.

I don't have ANY in mind. I simply rasied the point about the
incompleteness/inaccuracy/lack_of_reality in the original

statement(s).

YOU raised the consideration of noticeability.

Huh?

The return loss is always better with increased line loss.

Unless you go all semantic about the definition of VSWR and go
measuring voltages at each end, ignoring the line loss in between, which
you can't do unless you don't believe in conservation of energy.

>
>How?

Loss generally prevents the line from being purely resistive in
characteristic impedance. It is not distributed between shunt and
series components like an attenuator pad would be.

With a well matched load and a lossy line, SWR INCREASES with line
loss. Attenuation generally makes the line look slightly capacitive on
the source end, and will change input resistance.

We have to be careful picking nits. The nits we pick may be our own!

Could anyone please tell me how to make a simple or with only a few parts, a transmitter that can transmit 3km for treasure hunt, radio direction finding activities for the club.

What I was hoping for is to make a transmitter that would give a beep every second or so.

Thanks Craig

636. Transmitters

Would anyone know on how to make or design simple transmitters from some simple circuits or any books on the subject.

I have knowledge of electronics but find it a bit difficult when it comes to designing transmitters.

If there is any books on the subject I would find that most helpful.

Thanks Craig

Exactly! Take 100 ft (30.48m for our Australian friend) of RG-213
operated on (to keep Tom happy) 1.8 MHz. Assume a perfect 50 ohm
source and a perfect 50 ohm load.

The matched line loss for this line is 0.259 dB/100 ft. As Tom
correctly points out, this loss makes the line Zo deviate from a real
50 ohm to a complex Zo = 50 - j0.855.

When terminated with the 50 ohm load, the line is mismatched and
operates with an SWR of 1.016. At the input end, the SWR presented to
the perfect 50 ohm source is 1.033.

So our nitpicking friend from down under is wrong when he states:

"Whoa big boy! I repeat, and I'll try to use small words so you can
keep up: ANY loss will improve the match. ANY loss will give a
"better match". And anyone who can work out an R.L. can see how much
loss they need to get a certain improvement if the source end is
matched."

Clearly, here is a case where "increased" loss "did not" improve the
match.

In *my* thirty-three-plus years in the rf/microwave industry, I learned to NEVER make such unequivocal statements as these. There is always going to be that one overlooked item that reaches out a bites you in the ass.

I believe some apologies are in order.

Wes N7WS

What band(s)? You can do a reasonable small loop on 80 meters, and
probably even get it to work well on 40. Above that you may be better
off with other equipment. If you look in an antenna engineering
handbook (like Johnson and Jasik), you'll find a whole chapter on RF
direction finding, covering a wide freq range. I should also perhaps
ask if you want to do it mobile or from a fixed location, or what.
People with lots of real estate have built huge symmetrical arrays
which are steered by switching. I recently had a look at an RDF
system based on annular slot antennas which was relatively quite small
for the freq range it covered, and claims good accuracy, but then the
makers charge something like $50k for it, and the electronics runs in
a VXI cardcage.

Have you done a Google search for "HF radio direction finding"?
You'll get lots of hits.

Cheers,
Tom

Try looking at the transmitters in the ARRL handbook. Some are very basic and
cna be easliy modified for other uses.

642. Re: A very simple SSB receiver ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-21 20:49:49 UTC
From: dt@dt.prohosting.com
Message-ID: <uadpos6fm.fsf@dt.prohosting.com>
Source record: 43205

I'm working on a SSB receiver right now, and my choice is to use direct conversion, but use the Weaver phase cancellation method to eliminate the unwanted sideband. Strictly speaking this set isn't direct conversion but a single conversion superhet with a 4 kHZ IF and the phase method of image cancellation.

Basically it looks like this:

```
|---------|
/--MIXER--GAIN--| stereo |
ANT---FILTER---SPLIT-< | codec |-----AUDIO OUT
\--MIXER--GAIN--| and |
| DSP |
|---------|
```

Not shown are the two local oscillators. Both are DDS sinewave sources and they are programmed to be 4 kHz off from the received signal (in the same direction) and 90 degrees out of phase from one another (in quadrature). One DDS feeds each balanced mixer. (For a receiver with wide receiving range, DDS is preferable, and the input filter should track. For a narrow receiving range, it is possible to use a PLL to local a second oscillator in quadrature with the main one, thus avoiding the expense of two DDS chips.)

The output of each mixer is band-limited (in the DSP software) to 4 kHz. The result is that each mixer output contains the desired sideband and the image. In one case, the image is 90 degrees ahead, in the other case it is 90 degrees behind.

In the DSP, each channel is multiplied by a 4kHz wave, but the two 4kHz waves are 90 degrees out of phase. The products are then summed. The result is that the wanted sideband is reinforced while the image cancels. To change sidebands, just flip the phase of one of the 4KHz waves (and shift the carrier to the other side of center).

Interestingly enough, it is also possible to detect AM and FM with this topology, provided the DSP is fast enough. In that case, the local 4kHz oscillator (in the DSP) is phase locked to the incoming 4KHz heterodyne product coming from either mixer. The phase detector error signal is the FM demodulation and the sum of the multiplier products is the AM demodulated signal.

This approach is "simple" RF-wise, since very early in the signal chain you are dealing with audio frequencies. It is also "simple" in terms of overall parts count. Naturally, a lot is being done in the DSP so it isn't necessarily "simple" overall.

David

Skip!

Where did I say TETRODE??? I said there are better CERAMIC tubes.
A specific example would be a 3CX800 or 3CX1500, either will
beat the 4XC250 3rd order IMD specs by several dB. (-36 and -38 dB
respectively.)

Where did I say the 4CX250 didn't meet FCC specs for IMD?
I'd be interested in a reference to the FCC regulations specifing
transmitter IMD perfermence requirements that you referenced. If they
exist, then there are a lot of vintage sweep tube amps
still in use that are far worse than the 4CX250 in terms of poor IMD
performance.

Sure, 4CX250s may be cheap, but the problems and added costs involved
with the bias supplies, screen-regulation and protection circuits, and
even
finding good quality shielded-screen bypass sockets, sure make a good
case for using more modern components. My choice would be a 4CX350--if
I was constrained to whatever ceramic tetrode was most handy and in
quantity in my tube bins.

For reference:

http://www.svetlana.com/docs/TechBulletins/technoteNo42.html

It is clear that you only wish to argue. I don't.

647. Visio for schematics

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-22 09:21:05 UTC
From: "Sverre Holm (LA3ZA)" <la3za@qsl.net>
Message-ID: <5kXQ8.5241$c06.104523@news2.ulv.nextra.no>
Source record: 43210

Does anybody in this group have experience with Microsoft Visio for drawing schematics?

I have access to the 2002 version at work and am trying to use the EE module. It has a lot of nice features such as automatic rerouting when components are moved. But its set of templates is limited. Specifically I am trying to draw a circuit with an LM386 audio amplifier, but it seems that I have to start by making the symbol for the LM386 myself, i.e. an op-amp with some extra connections on the top and bottom. Any tips for how to do this in a simple way?

73, Sverre

Wrong again - but then again, what else should I expect?

The original discussion (up until this example) related to a line
matched at the source and mismatched at the load end. Using 52 ohm
line with 50 ohm terminations is shifting the goalposts yet again.

I've used ceramic filters in log IFs for spectrum analyzers without
problems. I also was lead
to understand that very sharp skirts (good shape factors) could lead to
problems in spectrum analyzers.

From the 2000 version on, I believe they are owned by Microsoft.

On the Microsoft site, there are often very useful add-ons for all of
their software. These are things which would clutter it up for most
users, but some would want, or were thought of after the release.

Worth a look.

Happy trails,

653. Re: HELP with Two-Modulus synth

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-22 14:03:11 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3d1482f8$0$7363@echo-01.iinet.net.au>
Source record: 43216

Ron
The NJ series were made by Plessey some years ago.I wasnt aware that Philips were still selling them. I once built a "proof of concept" synthesizer for the 2M band using these devices. I got it to work but it was unstable when I tried to FM modulate it for transmit and I gave up. I used the NJ8822 series version with a SP8793 prescaler. Looking at the datasheet for the 8821 it appears to be a 4 bit parallel interface. It looks as though you use pins DS0-DS2 to address the 4 bit data to the relevant register.
For 12.5 KHz operation at 144 MHz R (addresses 101, 110 ,111) would be loaded with 8400/12.5 = 672 = 2A0 Hex or 1010100000 binary - address101 gets 0000, 110 gets 1010 and 111 gets 0010

MA would be 144000/12.5 = 11520 or 2D00 Hex or 0001 0110 10 000 0000 binary
In this case I think address 011 (A counter) gets 0000, 100 gets X000 (X dont care),000 gets 00XX, 001 gets 0110 and 011 gets 0001

It looks like you use the PE pin to strobe the data.
The A data simply follows the M in calculating the overall main divider ratio
Bear in mind that M should be > or equal to A so there may be some illegal ratios higher up in the 2M band
The MC pin from the synthesizer goes to the prescaler to toggle the divide ratio
I dont have the data for the 8703 so I dont know the details of this device.
Hope this helps

Richard

The passed few days on my spare time, which is little I am afraid to say .I managed to do some home work on the 6146 (found RCA's 6146.PDF) and with your ideas and guide lines things are not so cloudy any more. I rounded up for starters all the parts needed a nice power supply (modern standards no bulbs) , the rectifier diode bridges are a bit of an overkill (KBPC3510) but could not find anything smaller (in amps).I did not want to use simple diodes for esthetical reasons . In a few days the transformer will be ready (custom ordered 15V 5A , 300V 1A ,400V 1A ,500V 1A) which is as well a overkill for this application , but since you cant order transformers everyday I got one for future projects as well .

The only cloudy part at the moment are the output coils (no data at http://www.qsl.net/n6ev/57-174S.jpg) does anyone have the data I need as well as the physical coupling layout of these coils?

> Does anybody in this group have experience with Microsoft Visio for drawing
> schematics?

<snip>

I have an older version (4.1 Technical) from before it was Borg'd (and, IMO, ruined) by Micro$platt. It works fine for simple stuff, or for mechanical layout drawings. If you're trying to do a schematic that you will want to, later, make into a PC board, or you need to simulate the circuit before building, you need to be looking for a more powerful package that is dedicated to EDA (Electronic Design Automation).

I've used several, and I've pretty much decided that it's a case of 'Use what works best for you.' Circuitmaker/Traxmaker, Protel, OrCAD, Electronics Workbench, Eagle, all have their good and bad points.

I suggest you pop a similar question on the newsgroup 'sci.electronics.cad' and see what you get back.

Good luck.

Curiosity, not criticism: how did you compute this? I can see you left
out the 0.4 ohm or so of the 100 feet of #12 center conductor, and whatever
resistance the shield might have; would it change the calculation to any
noticeable extent?

(Talk about picking nits...!)

Someone makes fundamental crystals past 125 Mhz. L-3 Com/Microdyne
used them in their tuner modules when I worked there. They were quite
expensive. (>$30.00) I don't know if I can find out who made them. They
just closed the plant to move it to Pennsylvania, and I've lost contact
with the ones moving, till they have the computer systems and E-mail
moved.

Forgive me but your last comment suggests that it is nothing but
criticism.

I didn't leave out anything despite what "you see". Where else do you
suppose the loss comes from if it isn't due to skin effect (resistive)
loss and dielectric dissipation. I gave the reference right in my
post or you can look up in any number of places the resistive and
dielectric loss coefficients and derive the line parameters for
yourself.

Ok. Since I am wrong, that means I misunderstood your
intention, and you are willing to post the answer.

Let me ask again: with the 12 feet of 52 ohm coax feeding the
50 ohm antenna, how much coax added to the line, at what
loss per 100 feet, will give a "real world" better match
in your opinion? "Real world" here is used to mean a
sufficient change in the SWR as measured by a typical SWR
meter so that the antenna installer will definitely notice
it.

Tracking this thread back as far as I can, the first comment I see
from you was:

"No, the exception is ANY line which has ANY loss - as they all do."

So you didn't seem to be limiting your comment to "the original
discussion" but making a general statement that was proven wrong.

Futhermore, I did not use a 52 ohm line; RG-213 is a nominal 50 ohm
line, at least in the northern hemisphere.

Why don't you just 'fess up and apologize.

How'd you get rid of the spurious responses above the fundamental? All of the ceramics I've swept look just awful. Lots of jaggies above the passband, barely 40-50 dB down.

> I also was lead
> to understand that very sharp skirts (good shape factors) could lead

Not that I'm aware of. Most commercial units have pretty sharp skirts. What sort of problems are you referring to?

Yep, he was clearly worng.

Adding loss to a transmission loine that is nearly perfectly matched
will increase SWR, he just doesn't grasp the concept yet.

>Futhermore, I did not use a 52 ohm line; RG-213 is a nominal 50 ohm

Sorry, unintended. I meant that 0.4 ohms is kind of a tiny consideration
given this scenario.

Source record: 43229

As an aside quesion .. can crystals at these fequencies be used
in lattice filters .. I have a design in mind that requires conversion
to
a first if of something in the region of 70 to 150 MHz .. the
narrowest filters I have found are 30 khz from the if stages in cell
phones .. operating
about 80 MHz .. this design is for cw and ssb so ideally
would like it narrower than that .. and ideally tunable via vericap
capacitance
to alter the bandwidth

Thanks

Source record: 43231

I'm just getting back into radio after an absence. In the meantime I have picked up microlight flying as another great way to enjoy oneself/spend money.
The Icom-A4 handheld I have installed in the aircraft works well but the standard Icom connections for a headset and mike are a collection of cables and cable sockets. They rattle around all over the place and are fiddly to connect up every time I want to take off. (I don't leave the radio parked in the plane) so I'm building a simple jiffy box with all the sockets in (PTT, mike, phones) and a single lead to the Icom. Maybe later I will add a switch so I can go from the av band to a 2-meter rig in flight, but that's another road .. .
Problem is I have found no supplier yet (in New Zealand) for the 4-pole 3.5mm jack plug to connect to the transceiver. (Like an audio stereo plug, with an extra stripe)

Where can I find a couple of the plugs, and somewhere on earth where the postage/freight won't cost me 10 times the plug price . . .

Stop being so deliberately obtuse. Wrong again means that I have no intention of feeding your argument trolls. YOU introduced the "noticeably better match". Let me repeat:

Tom stated:
"If the line is 50 ohms, and the load is mismatched, there is NO length of 50-ohm line that will cause the impedance to be a better match to 50 ohms.".

I repeat, the above statement is ONLY true in a lossless line situation.

The O/P referred to 12 feet of real line, not lossless line. Tom's para did not specify lossless line. He was replying to a real world question.

You can ask all the questions you like. I will not be baited further.

I remember reading somewhere that overtone xtals can be used in ladder
filters. The design process is probably rather tricky. They are obviously
used in VHF lattice filters.

673. Tandem Match directional coupler

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-23 18:21:45 UTC
From: Peter <pa5ke@euronet.nl>
Message-ID: <af53lv$2ch4$1@beast.euro.net>
Source record: 43236

Dear OM,

I am intending to build the Tandem Match directional power SWR meter. I would appreciate it if somebody can help me with the following questions.

I have a question regarding the transformers in the directional coupler. In the ARRL handbook 1999, page 20.40 I read that the Amidon core is type T50-3. This core is however specified to use between 0.05 and 0.50 MHz. The Tandem Match is specified up to 54 MHz (?).

1) Is it indeed so that the T50-3 is specified or is this a typing error in the ARRL Handbook?

2) The T50-3 is difficult to find overhear T50-2 or 6 are much more common, is it possible to use one of these types in the system without changing something in the way to build the Tandem Match. (eg. the number of turns on the core).

3) I have T106-2 and 6 available. Can I use one of these together with RG213? Can you say something about the number of turns needed if this core is usable to reach the same specifications?

I hope somebody can help me with this questions.

Thanks for reading.

Wrong set:

The Icom aviation handheld IC-A4 mentioned in my original post should be an IC-A5. Sorry about the finger trouble. The A4 has a 2.5mm and a 3.5mm socket, not a single 4-pole socket.

So I'm still looking for a source for the 3.5mm 4-pole plugs.

Everything. Whether you or I like it or not, it happens everyday on the CB. Everything that occurs on CB can be discussed here. I would rather they do it correctly and safely if they are going to do it at all.

Would you go to a drug users group and whine that what they are doing is illegal? Would you prefer they have to hide from you, and because of that, they get the wrong information and die because of you? That's all you're doing here.

If they don't know how to do it safely, don't you think that will
prevent many of them from doing it at all? Probably not...

But if you are so concerned about safety, maybe you should be thinking
about these dipwads handling a full amp at a thousand or more volts.
I'm sure you are aware that it takes far less than that to be lethal.
And why haven't you posted anything bleeder resistors? Or about HV
insulation properties? How much risk is there for fire when no
consideration is made for arcing? Have you mentioned anything about
unshielded high-power RF used in close proximity? In all your posts
have you ever mentioned the "one-hand" rule? Or how about rings?

And BTW, it doesn't matter what kind of IMD figures your tube has if
the harmonics are coming from the previous stage. What are you using
for a driver? Are you using a tuned input or are you trying to skate
by with a swamping resistor? Could the harmonics land on an emergency
pool frequency?

No, Scott, you are not concerned about safety; that's just a ruse to
justify your illegal intentions.

>Would you go to a drug users group and whine that what they
>are doing is illegal? Would you prefer they have to hide
>from you, and because of that, they get the wrong information

If they foolishly mess around with stuff they don't understand but
know could be lethal, then they deserve what they get.

What are you trying to accomplish?

How many hours of development is worth $200?
You can buy really decent APs for under $200.

For me, the build vs. buy decision takes about 30 mS: buy.

685. Help for a friend with an ICOM IC-751 Transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-24 05:20:58 UTC
From: John Boyle <john.boyle@erols.com>
Message-ID: <3D16AC3A.94AC4D7B@erols.com>
Source record: 43048
Cross-posted to: alt.ham-radio.packet,free.uk.amateur-radio,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.shortwave,uk.radio.amateur

A friend who doesn't have access to newsgroups asked me to post this message for him. Please forgive me if I've posted to this group in error.

Concerning the ICOM IC-751 Transceiver, my friend asks:

"...In that radio is a ram-board that contains the operating system for the radio and that's where memory channels are stored. I need the hex code for that radio. I believe the board has a total of 1024 bytes of memory. I think the first 256 bytes is for the operating system and the remainder is for user memory storage. I need the first 256 bytes.... maybe you can put this request on the news groups and some Ham out there might have the code and can send it to me at W2RB@JUNO.COM..... it would be greatly appreciated... tnx.."

If someone can help him, you can email him directly, or email me and I'll get it to him.

Thanks.

John

==========
Ten-Tec makes or made a similar HF transceiver 'Pegasus' , as advertised in QST .
However lately they only advertised their (new) Jupiter HF transceiver.

Does this mean that 'blind boxes' which require operation through a PC are not all that much in demand?

They obviously have a purpose when used as a remote station ,like the 'super stations ' in California (LA-Brea) where users can operate HF from a handheld VHF radio.

Yaesu's new handhelds use these as well, as do some camcorders and walkmen. They've been occasionally sold on eBay, with the description of being for Yaesu handhelds--that's where I found mine. Beyond that, I haven't been able to find them anywhere either. I wouldn't have a clue where to start looking in NZ if you don't want to mail order... Hope the info helps, though, and good luck!

The article is about fabricating a mixer to convert 100KHz to 60 MHz up to 100.1 to 160 MHz.

In this mode with the converter, you don't have to worry about the hundred digit. The circuit takes a 100 MHz input from a crystal.

I assumed this would be fundamental mode. Maybe it can be overtone mode.

Glenn,

Since you didn't meant a callsign or license class, I wonder if your first step is to get licensed. In the UK you might like to get a new Foundation license to get you on the air (with commercial equipment or approved kits) and then you can work towards a Full A license. The getting on the air helps you get active and gain practicall on the air experience, which I find it one of the best ways to learn.

Contact a local amateur radio club <http://www.rsgb.org.uk/clubs/clubs2.htm> or the RSGB <http://www.rsgb.org.uk/getlicensed/getlicensed2.htm> for more details about licensing in the UK.

QRP is certainly a more economical way of getting started on HF. Not so many people build/buy QRP style transceivers for VHF (e.g. 2m, 70cms) preferring typically to buy a used radio. Find a local club, and the experienced hams will be able to give you more specific advice, and might even point you to a decent used radio at a good price, after you get/are licenced.

When I started, I got equipped for about 200 quid. I was able to buy used equipment that served me well enough to get started, and since then I've spent more than a few more quid since. :-)

There are some SSB HF capable QRP rigs, but they are more complex than the bare bones CW HF rigs of course to produce and receive SSB.

There are some kits available such as the Elecraft K2, Small Wonder Labs White Mountain, Epiphyte-3, or the lovely factory built Yaesu FT-817.

Any old 100 MHz clock oscillator will do that job. See Jameco catalog or if you'd like, I have a few and could send you one. The postage is about the same price as the clock.

695. new-basement construction grounding suggestions wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-24 17:06:33 UTC
From: mcalhoun@ksu.edu
Message-ID: <af7jip$8jm@unix1.cc.ksu.edu>
Source record: 43058

In a couple of months, a contractor is going to move my house into the front yard, replace the old/cracked foundation and partial basement with a nice new full basement, and then move the house back into place.

My ham "shack" will be in one corner of the new basement. I shouldn't have trouble getting wires/cables through the new concrete walls, for we've already agreed that, instead of patching the four holes through which the house-lifting beams will go, he'll frame and cover them with wood so I can use them later for wires and cables. There'll also be three "egress window" openings in the concrete, and I've specified that he should leave a few-inch section of wood next to each window for later drilling through.

I'M LOOKING FOR SUGGESTIONS ON HOW TO PROVIDE A GOOD EARTH GROUND FOR MY SHACK. When I told my contractor that--just before he backfilled around the outer walls--I wanted to drive several ground rods here 'n there outside the footings and run heavy wire up the walls to the above-mentioned openings, he volunteered that he could even leave "sleeves" in the basement floorslab itself through which I could drive ground rods. (In other words, he's quite cooperative!)

So how many ground rods should I drive in, and how long (the bottom of the excavation will be about 7 feet below grade), and where, and should I connect them all together, and with what, and should they be spaced all around the house or mostly near the hamshack. Or, instead of driving 8-foot ground rods, maybe I should bury some copper "sheets" (like roof valley flashing?) in the soil at the outer edge of the digging? (Or will that relatively-thin stuff corrode too quickly to be of any use?)

Or ....????

Incidentally, I've been told this area is underlain by a clayey-sand for some 50 feet or so downward beneath a foot or two of good topsoil before a limestone ledge is reached. We are also about 20 feet above what becomes a river bottom in a 100-year flood.

Even though we are in Kansas, I'm NOT expecting total lightning protection. I also don't want to spend more than a few hundred dollars on this aspect of my hobby (the basement project, itself, is going to be expensive enuf!) I'm just looking for good ideas.

It actually used a NEC uPD444 which is 1024 x 4, so 512 bytes.

>> I think the first 256 bytes is for the operating system and
>> the remainder is for user memory storage. I need the first
>> 256 bytes....

A couple years back I replaced the backup battery in my 751A, so
my radio is still alive. At the time I saw a couple replacement
boards that were available but never saw the memory image posted.

With a search today, I found this site.
http://www.geocities.com/emailsrikanth/ham/icomram/RAM.html

It looks like this has the information you are looking for.
Specifically, the file 745_751.zip.

Now I am prepared for a future radio disaster too.

Well, Skippy, I posted links and some figures based on manufacturer's
data from their websites and from their databooks. I also stand by my
posts, which you continually misquote. Read what I posted and try to
comprehend. You're obviously trolling, since you have offered absolutely
nothing which refutes what I originally said "they are better **ceramic**
tubes than 4CX250s [for IMD performance] for amplifier use." You asked
for figures and data, other than from "obsolete radio amateur handbooks",
and then you continue to argue that the data taken from the manufacturers'
own
websites is flawed, based on your opinions.

I suggest that YOU trying to provide some concrete facts, based on concrete
technical that has been published. And sorry, not all external anode
tetrodes
have the same IMD performance despite the "size of their anodes". I'm
still waiting for you to quote the FCC regulations that specify transmitter
IMD
performance, which I suposedly alluded to.

No rods. See "Ufer" ground on google.

Essentially you want to connect all the rebar in the floor and walls
(preferably weld, but double-tie and extra tight is not too bad) and
leave a rebar poking out long someplace to connect to.

Then, to get even more extreme, create a "ground ring" around the
building. I'd do it outside, not thru the floor. Space it away
from the foundation, I'm not sure how far. This ring would be
composed of rods driven at every 20feet or so all around the
perimeter of the foundation. All rods should be connected together
via #4 or #2 solid copper. Use "bury approved" clamps and put the
entire thing down below grade.

Bond the Ufer and the ring at one spot with #4. Tie to that spot as
your electrical system ground and everything else that needs
grounded. (I'd prefer to start the #4 for the ring at that spot,
and when you get back to that spot continue to the rebar then to the
electrical panel. One continuous length of #4 is better than a lot
of connections.)

I supplied data for several ceramic tubes. You have a fixation on tetrode
4CX250s. Read my original post.

>We were talking about converting an original sweep tube layout
> to use some NOS 4cx250b tubes when you piped in with your IMD blanket
> statement crap, which reads like you've spent five minutes in some vintage
> handbook with dated information.

Yes, of course your right. Any sweep tube amplifier is a natural for
conversion
to external anode tetrode amplifier tubes. Small matter of pressurizing the
chassis
and meeting the plate, bias and screen voltage requirements. Skipp can
make a
4CX250 amp with as good 3rd and 5th order IMD performance as any of the
3CXxxx tubes, 'cause it says so on his webpage.

The FCC has no test requirements for IMD, or standards, in amateur
service. they do not ask for that data in type-acceptance, and care
less about it at that end.

The only requirement is on the USER to be sure his station meets "good
engineering practices" signal quality. You are not allowed to have
any modulation products extending outside the authorized frequency
limits for your class of license of for that mode, and you are not
allowed to cause interference on adjacent channels.

Factually, nearly all radios being sold today do NOT meet FCC
standards if we consider "good engineering practices". For example,
the TS2000 is a pathetic -30 to -25 dB or so below PEP for third order
on 160-meters. Other radiaos are similar, look at reviews. Remember
also the ARRL uses dB below PEP, and NOT the industry standard dB
below one tone. The published data by them is six dB better than the
standards used by commercial people.

An old Collins KWM-2 I have is almost 30dB BETTER for IM3 than a
modern TS-2000.

With all that in mind, 4CX250's are generally better than some modern
rigs and worse than others when properly run, with well-regulated
voltages on the grids. Without regulated voltages, they are trash.

But a good screen supply is required, and protection and metering
circuitry for the screen is an absolute requirement.

Amen. Sevetlana's main goal was selling tetrodes even if it meant
stretching the truth with creative marketing.

If you need an example of this, look at measured IM performance of
PA's using their tetrodes in well-designed PA's like ten-Tec and ETO.

Despite Svetlana's jabbering about how tetrodes don't need good screen
regulation and are clean clean clean, they fail to meet those claims
when compared to simple cheap triode PA's.

NEVER depend on marketing oriented literature for reliable technical
facts.

I would recommend the use of copper tape instead of wire. As we know,

AC travels on the surface of conductors. Tape provides more surface area. In fact, a 3" tape provides the same surface area as a 1" diameter wire (approximately> I know abour pi). Also, bond all ground systems together with mechanical (or eutectic welds, if you can afford it!).

Judging from some of the other threads I've been reading here, you're probably right. Why are so many people so uptight about trivia? Ham radio should be fun or, at least, it used to be.

The 10 Mtr antenna is easy as far as I'm concerned. Go buy an 8 foot whip from Radio Shaft and cut it 'til it's matched. Works okay, but won't win awards for elegance. Probable efficiency is 0 dBi. The residual VSWR (guessing < 2.0) won't hurt even a rice box. ;-)

I have a couple of attenuators from a HP8555 RF Section and I'm needing some help with hooking them up. They have some feed-thru caps on top of the units and I'm assuming those select how much atten. the unit presents. Does anyone have schematics that could be emailed? I'm only wanting to know what the input voltage is and also the pinouts of it the attenuators. I also have a A4 1st Converter that I'd like to know anything available about it.
Thanks!!!
Mark

Definitely. Difference in potential between different grounds is a
good way to destroy your equipment and perhaps worse.

I've seen insulated wire, buried, to do bonding. The screenhouse and
my pool filter in Florida were bonded to the service entrance ground
with ~#6 insulated wire???!!! For buried, thinking about it, I see
why to use wire. As for code, I don't know but code can be exceeded,
can't it? Back up the wire with strap.

What your concern is with burried copper tape? Is it because the
relatively-thin copper tape may experience lots of corrosion in
damp clay-ey soil?

I'm considering using old coax cable (I've already torn out many, many
feet of that stuff!); the insulation may protect the copper shield,
and the shield plus center connector are, combined, pretty big.

Message-ID: <afai6sjlc5@venus.btinternet.com>
Source record: 43075

New program PADMATCH.exe

For given source and load resistances this program designs T, Pi and L resistive matching pads and attenuators. It has the same facilities as program MatchPad (which it replaces) but with an extra facility to insert preferred-value resistors from the various standard tolerance ranges. The design procedure is used in reverse to predict the in-circuit attenuation (dB).

First calculate the ideal resistor values of a network. Then replace them one-by-one with the nearest preferred values and the changed attenuation will be automatically calculated.

Hi, Mark --

The 8555A attenuator sections are 10-20-40 dB. You apply 12 volts of
one polarity to enable a section, and reverse the polarity to disable
it.

That's from memory. It might be +/- 15V, and I don't remember if it
requires a sustaining voltage or not... I'll check the manual when I get
home. If so, then it expects a few volts (~5) to be kept applied to
each actuator to hold it in the selected position.

Easy enough to tell which section is which... just put it in front of a
receiver with a strong signal coming in the other side, and enable each
section in turn.

Aaron,

I enjoy really reading these technical debates and have always had a fascination with amplifiers of any
type, from audio to LASER.

I just searched my newsgroup provider for the text string 'amplifier' and found no matches.

If there was a rec.radio.amplifier newsgroup I would prefer to be there.

This group seems to be the next most popular for those types of discussions.

If you look at this thread, the majority of the posts have been made by licensed operators who just may
have been drawn here to this newsgroup because their interests are similar to mine.

If a new newsgroup titled rec.radio.amplifier was created, and those folks interested in having amplifier
discussions went there instead of to rec.radio.cb; would it finally satisfy you to the point were you
would......
1) Just leave us alone on that other newsgroup?
2) Stay on rec.radio.cb and continue to act as the 'conscience' of the entire newsgroup?
3) Or would you join us on that amplifier newsgroup and make some on-topic posts that would contribute to
the overall intelligence being shared?

I could embrace any one of the three......

Regards,

Dennis O.

GOOD GUY ALERT W2IJL
I made a road trip from NC to Waverly NY over the weekend.
Meet Allen W2IJL. What a wonderful Ham! I went to pick up an amplifier,
He meet myself and David KA4VNG at the door, welcomed us into his
home, His lovely wife rustled us up something to eat after our 12 hour
drive.
Then he proceded to show us his treasures. When It was all said and done
we loaded my van full of all sorts of goodies. Yes if you have the
pleasure to meet Allen he is a man of his word. And one heck of an
amplifier builder. Boy was it a long 28 hours, but we sure had fun!!!

>
>I just searched my newsgroup provider for the text string 'amplifier'
and >found no matches.

That's funny, I found matches in...

rec.radio.amateur.equipment
rec.radio.swap
rec.radio.amateur.contesting
rec.radio.amateur.homebrew

Maybe there is something wrong with your browser. Also try e-Hamnet, QRZ.com and the contest reflector. Of course, these are all topics pertaining to LEGAL use of amplifiers. If you seek topics dealing with ILLEGAL operation of amplifiers, try these forums...

Uncle Jims Radio Page
BigRadios.com board
Keydowns.com board
Lowriders CB Board
Davemade board
Noname Amps Board

...etcetera.

>If there was a rec.radio.amplifier newsgroup I would
>prefer to be there.

Fine. But as I have demonstrated, you have plenty of more appropriate choices to share your knowledge of RF amplifiers in than a "CB radio" newsgroup.

>This group seems to be the next most popular for those types of
>discussions.

Check out the list I gave you (above). I think you'll find 100x more amplifier discussions going on in there rather than in here. If quantity and number of amp discussions was your goal, you'd be somewhere other than rrcb.

>If you look at this thread, the majority of the posts have been
>made by licensed operators who just may
>have been drawn here to this newsgroup because
>their interests are similar to mine.

I have no wish to regulate your posting or regulate discussion. I am merely commenting on the fact that a CB newsgroup is being used to discuss equipment that is illegal for use on CB radio.

> If a new newsgroup titled rec.radio.amplifier was created,
>and those folks interested in having amplifier
>discussions went there instead of to rec.radio.cb;
>would it finally satisfy you to the point were you
>would......
>
>1) Just leave us alone on that other newsgroup?
>2) Stay on rec.radio.cb and continue to act as the
>'conscience' of the entire newsgroup?
>3) Or would you join us on that amplifier newsgroup and
>make some on-topic posts that would contribute to the overall
>intelligence being shared?

Regarding #2, I am merely posting my opinions. Do you have a problem with that?

Regarding #3, You need to check out all those forums I gave you that exist to discuss illegal CB. I do not post there, nor do I have a wish to. I believe that answers your question.

Regarding #1, If you found or created an official Usenet newsgroup called "rec.radio.amplifiers" you would inevitably find yourself sharing discussions with licensed amateurs. I'm sure there would be friction when they got wind of keydowns, 20K CB amps, freebanding, and the like.

Here I am,
Many thanks to all the many responses and debates about the 10M
antenna.
I did not expect this much response to my question. Since I've posted
the question, I have still been using the magnet mount cb antenna that
has been
mounted on top of my mini van. It is a radio shack type wound by a
wire almost to the top and wrapped around plastic (helical?). It comes
tuned from the factory and can not be tuned. The reception is much
better than tranmission with results being a couple of contacts in the
15 - 20 mile range locally. (NO DX yet on the mobile) Correct me if
I'm wrong, (and I'm sure someone will!) it sounds like I can set up a
tunable cb helical like a firestick,and use an antenna tuner to obtain
the best match. But now, here is another debate. Will a simple
homebrewed tuner work? (a coil with a var capacitor?)
Anyways, I had a great time this weekend with field day while I was
doing some work around the house, I took some breaks and fired up the
htx-10 for some contacts. It was my first field day since I just
started, earning my Tech in April and General in May. Only made
contacts with stations east of the Mississippi as far north as
Ontario, and as far south as Brazil! all on 25 watts. I have a
homebrewed dipole at a 45* angle. Maybe I should make another one with
thicker wire. The one I use now is about 18awg. Does thickness matter?
Oh well, so much to learn and so little time to enjoy it!

>
>Or ....????

Read up on Ufer grounds before pouring the new foundation! The
National Electrical Code calls these "concrete encased electrodes". If
you can, make it a loop all the way around the new foundation. Details
are available from Polyphaser:
http://www.polyphaser.com/datasheets/PTD1030.pdf.

Since your utilities will be disrupted while the house is being
relocated, this is the time to implement a "ground window" for every
conductor coming into the house, all properly bonded to your new Ufer
ground system.

Good luck!

If you are burying it to get rid of it that's one thing. If you are
burying it for a ground you don't
want insulated wire and you don't want stranded or braided wire. Only
solid wire should be
used in the ground or out in the whether.

The electrical code allows solid bare or insulated green cover wire
for connecting grounds
together. They don't care if they are buried or not. Their purpose is
tying to a buried ground
rod.

Many of these "wire wound" antennas can be tuned. They are just a
fiberglass (or plastic) pole wrapped with wire and covered with heat shrink
tubing. To tune you pull off the cap at the end to expose the wire, and
peel out a little at a time and snip. Obviously with this method you can
only go up in frequency, but going from 11m to 10m that is not a problem.

730. Advice on VFO packaging

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-26 11:31:49 UTC
From: "G. Milligan" <g.milligan@coventry.ac.uk>
Message-ID: <3D19A625.94030DE4@coventry.ac.uk>
Source record: 43093

I am currently building a HF Colpitts VFO based upon the article "A High Stabililty VFO" that appeared in Practical Wireless Oct 1987.

I am looking for advice on how to mount the PCB board and coil. Should I be looking at rubber mounts, epoxy resin or candle wax to secure the parts against physical vibration, how would these different compounds affect the dissipation of heat and thus frequency drift?

Assuming I place the entire vfo circuit in its own metal case, how does one compensate for additional inductance placed upon the coil due to the proxmity of the metal case? Is it just a case of trial and error, whiping the lid on and off and adjusting the LC?

I plan to use a 6:1 reduction drive, although I have two of these units and had originally planned to cascade them, would a 36:1 reduction be a bit overkill?

The vfo will be mainly used for CW and FSK modes, hence some degree of stability and fine tuning is required.

Any suggestions and comments would be welcome.

Thanks.

The simplest way is to mount in a rigid sealed box eg diecast aluminium.
This increases thermal inertia also which reduces short term temp drift.

You could also stabilize the VFO with a PLL scheme
see http://www.iinet.net.au/~richardh/VK6BRO.htm

You will obviously need to look at voltage and load regulation also

>

use a trimmer accessible through a hole in the box with the lid on.

>

This depends on the frequency span - 10-25 KHz per revolution is probably
reasonable.
You could also do a bandspread using a small varactor across the VFO tank
with a pot for 5-10 KHz fine tuning
I have done this for a homebrew QRP HF SSB rig

Corrosion or other physical damage. All the copper tape I've seen
is thin and quite fragile compared to a #4 or #6 wire.

> I'm considering using old coax cable (I've already torn out many, many
> feet of that stuff!); the insulation may protect the copper shield,
> and the shield plus center connector are, combined, pretty big.

Might work. There is some argument on braid being high impedance to
spikes.

That reminds me.

I have several dozen three prong and four prong vibrators in a bunch
of new old stock tubes and parts I acquired from a local TV shop.

If anyone needs one, let me know.

Tom,

Hey.. you got four prong 6V vibrators? I could use at least one, maybe two,
depending on cost. Please get back to me with cost/availability.

Thanks.

Take care, and stay well.

PS I sent an e-mail, and it got bounced.. :(

Hi Sylvan:
Instead of trying to deal with wire, braid or tape. Investigate the use of 1/4" soft copper tubing to bury. I priced it out as opposed to #6 bare cable. Much cheaper in Canada.
I use it for reduced noise in sensitive ULF communication circuits.
It can be perforated to accommodate the injection of magnesium sulphate or calcium sulphate solutions to increase soil conductivity.
I would do this well away from the house, as the sulphates can cause corrosion in the concrete, unless it is type 5 sulphate resistant.

best regards
Clark Southoff
VE6 some day soon.

==========

Although I don't know a specific source for this material , I have seen 25 x 3 mm
(1" x 1/8") copper strip used for heavy duty earthing systems .
It is also used on the ridge of sloping roofs to combat moss which grow on roof tiles. Rain carrying traces of anorganic chemicals causes the copper to react with the compounds . The resulting traces of copper compounds dissolved in water subsequently kill the moss .
BTW For the above duty any thick (bare) copper wire /braid / strip will do the trick .

Sorry for the digression , but I thought the info might be useful for house owners pestered by moss on their house roof.

The trouble with a high voltage zener diode is the temperature coefficient of voltage is highly positive. So the output will drift up as it warms.

A better approach would be to use a series string of low voltage diodes. This would also reduce the need for heat dissipation, as the power would be distributed over all the diodes.

The lowest uncompensated temperature coefficient of voltage occurs when the zener voltage is about 5 Volts, but a decently low drift would occur with anything below about 12 Volts.

Another approach might be a VR tube. Yes I know it's not a semiconductor but these things have low drift and are very rugged. You can combine a 150 Volt 0A2 with some zener diodes for a nice 200 Volt regulator.

How much current is needed, and what is the range of the source Voltage?

Bob

I've seen zinc advertised for that task and it is simply zinc sheet
metal (well under 1mm), the same stuff as used for zinc flashing. I
would expect any copper for that purpose would also be sheet metal
like the copper flashing.

Sylvan,

The copper strap that PolyPhaser sells is considerably thicker
than flashing material. It is approximately 0.05" X 3" or X 6".
These will form a low-impedence path equivalen to a 1" or 2" diameter
wire, respectively.

I've used successfully a HV transistor used in TV sweep circuits. Fairly cheap at a few bucks. Used as a series pass regulator. It provides the 250vdc for my T4XC (since 1980) quite reliably. I load tested years ago and have the data and schematic around someplace if you want it.

That is rather heavy weight for flashing... But 0.05" is the
thickness of 18ga steel sheet, less than half as thick as the 3mm
(about 11ga) stock mentioned by Frank. I know thick isn't necessary
for low impedance at high frequencies, but thicker sure helps
physical robustness.

There are some high voltage regulator ICs made for televisions, I am not in the
repair field but a lot through the NTE website might reveal some useable devices.

I haven't tried this myself, but...

The National web site has some information that might be useful.
Check out http://www.national.com/pf/LM/LM117HV.html and download
the spec sheets and the LB-47 application notes.

According to the information there, there are at least a couple
of possibilities:

1) The LM317HV is limited to a 60V input to output drop. But it
is floating wrt ground. If you limited your unregulated input
to 260V or less you could use it directly. However, you would
not have short circuit protection.

2) The LB-47 gives some useful high voltage regulation circuits
using the LM317HV plus additional pass transistors and passive
components.

it is usually better to use many lower voltage zener diodes in series,
say 24 or 47V, it is also better for cooling

I have made some shunt and series regulators with transistors and
valves up to 300V, and one has been in service over 25 years with no
problem for stabilizing screen-grid supply for my power amplifier -
this used a uA741 and 6AQ5/EL90/6005 valve. Voltage could be varied
150-300V.

From: akwusmc@aol.com
Message-ID: <3d1bb1f0.15774813@news.tn.comcast.giganews.com>
Source record: 43028

All,

I'm a new ham, and my first radio is a dual band HT. Obviously, I'm disappointed with the perfomance from inside the house, so I'm looking on the web for homebrew antenna projects so I can hit the club repeater.

I've looked at j-poles, dipoles, and yagis from 2-7 elements. The copper tubing j-poles (http://www.arrl.org/tis/info/JPole-V.html) look the easiest, until I came across a direct-connect 2 element beam (http://www.qsl.net/w4sat/tiny2.htm). Three pieces of 1 inch aluminum tubing, and solder your feedline. but since I plunked the dollars for the HT, XYL is sensitive about the costs. I can get 2+ sticks of copper tubing for what the local Ace wants for aluminum.

What are the pros and cons of these two types of antennas, what is the significance of the diameter of tubing, and could I not substitute copper for aluminum - why or why not.

TIA, and 73

Anthony, KG4TBO

Try using a Texas Instruments TL783C. It can pass up to 700 mA (TO-220). Just be sure that you don't accidentally short it out, since the maximum safe voltage across the device can't exceed 125 V.

Also try VM03 by ST Micro. It's an improved replacemnet for the now obsolete Harris HIP5600. You can put 450 V across that one, but I'm not sure if it can handle the current.

There are 'lots' of j-pole designs using copper plumbing pipe.
I suggest you do a search and pick some that look likely to you.
I took a quick look but decided there were too many for me to suggest
one.

A search for "j-pole" returned 4290 hits
so I narrowed it to "j-pole+copper" and got it down to 757

There should be some there to answer your questions.

I've seen quite a few copper j-poles, and have a couple of copper pipe
dipoles myself for UHF use.

Regards,
Dave

Message-ID: <03QS8.331104$352.37732@sccrnsc02>
Source record: 43032

I have a large quantity of new right-angle male SMA connectors with a 7" length of 50 Ohm RG-188-size cable attached, prepared and tinned at the free end. The cable is just like RG-188 except blue in color with a solid center conductor. Shield is braided. The connector has a press-in insert - not screw-in.

Mouser sells similar connectors for $4.89 each in quantities of 25. I'm selling bags of 20 pieces for $10 postpaid. Email for pictures.

Aluminum will not corrode anywhere near as fast as copper will.

I remember years ago a Nasa contractor did a test of different antenna materials and posted to the Fido ham message group. He found that there was a slight difference in length required for elements, but without precision measuring equipment you won't see the differance. When tuned correctly the different materials he tested - copper, aluminum, bronze, stainless steel all worked as antenna elements, but due to the weight consideration he recommended aluminum as the material to use.

Use what is available and that you are comfortable working with: welding rods, copper hot water pipe, aluminum arrow blanks, etc.

I built a 6 meter jpole out of 1/2 in copper pipe and a 9 element yagi for 440 out of aluminum ground wire and heavy copper wire.
thanks, John.

Firstly, the reference standard here is the simple ground plane antenna. It has a gain of unity. Both the J-pole and the beam have gains greater than unity. The difference is: The J-pole is omnidirectional and doesn't require a rotator, but does not have as much gain as a beam. If you are only intending to work the local repeater, either antenna will do. You will have to justify the increased cost of a rotator etc. which would be needed with a beam.

As for material, copper pipe is great for a J-pole. It solders up easily and is fairly sturdy. You should tape the coax connections and spray or paint the works with some kind of sealer to reduce corrosion. Aluminum is less corrosive, but you can't solder it so you need to bolt it, and it takes the same anti-corrosion treatment unless it is anodized. (In which case you have to grind, scrape or file it to make an electrical connection.)

Hope that helps.

Aaron will never be killfiled by many of the keyclowns because he speaks the truth, and truth is what most of them fear. IOW, anyone sitting on the fence is reading both sides of any argument, and can tell the difference between keyclown BS and the truth. That's why the keyclowns must keep shoveling more and more BS to try and cover up the truth as revealed by Voobner (and others).

And why would they do that? The obvious reason is that illegal operators depend upon each other to validate their illegal activities. Just like any other form of organized crime (or religion), it is social support that justifies their behavior. Things such as "logic" and "facts" diminish the persuasive effects of such anti-social reinforcement, and must therefore be contradicted.

Another reason is that some of them make a lot of money scamming people by convincing them to buy illegal amps and "export" radios. Opposition to these people has led to many, many threats of violence against Voobner, myself, and other defenders of honorable intentions. But many of us don't scare very easily, and will continue to educate people about the reality of radio communication (life is not an RF drag race).

Killfile Voobner? Ain't gonna happen. Deal with it.

akwusmc@aol.com wrote:
All,
I'm a new ham, and my first radio is a dual band HT. Obviously, I'm disappointed with the perfomance from inside the house, so I'm looking on the web for homebrew antenna projects so I can hit the club repeater. I've looked at j-poles, dipoles, and yagis from 2-7 elements. The copper tubing j-poles (http://www.arrl.org/tis/info/JPole-V.html) look the easiest, until I came across a direct-connect 2 element beam (http://www.qsl.net/w4sat/tiny2.htm). Three pieces of 1 inch aluminum tubing, and solder your feedline. but since I plunked the dollars for the HT, XYL is sensitive about the costs. I can get 2+ sticks of copper tubing for what the local Ace wants for aluminum.
What are the pros and cons of these two types of antennas, what is the significance of the diameter of tubing, and could I not substitute copper for aluminum - why or why not.
TIA, and 73
Anthony, KG4TBO
There are 'lots' of j-pole designs using copper plumbing pipe. I suggest you do a search and pick some that look likely to you. I took a quick look but decided there were too many for me to suggest one.
A search for "j-pole" returned 4290 hits so I narrowed it to "j-pole+copper" and got it down to 757
There should be some there to answer your questions.
I've seen quite a few copper j-poles, and have a couple of copper pipe dipoles myself for UHF use.
Regards,
Dave
==========
You can also build a J-pole out of 300 ohm TV twinlead, or 450 ohm "ladder line". They will not have the bandwidth of one assembled from copper pipe, but should be usable over entire band. Enclosed in PVC pipe they are suitable for permanent mounting. I am a scouter, and my walking stick antenna was very popular at the '93 National Jamboree, Where I was part of the K2BSA staff.

I also own a 2 meter dipole made from 2 19" lengths of 1/2" copper pipe. The center "insulator" is a PVC T. The copper sections are mounted in suitable (READ REALLY TIGHT) reducing flanges that is glued into opposite ends of the "T". I use rope in trees in scout camps to mount mine when in use, so I do not bother with the mounting possibilities, but the unused section of the T provides a way to more permanently mount

the antenna, with a little thought it should be easy enough to provide
for easy changes from vertical to horizontal polarization if desired.

I second that. Perfect regulation, no ripple. But I've got through 5 or
so of them by accidental shorts. Might be some way to protect it.

789. Experience with charging Ni-MH batteries

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-28 23:06:34 UTC
From: derek_toeppen@agilent.com
Message-ID: <2219e080.0206281506.39496894@posting.google.com>
Source record: 42950

I am looking for experiences people have had with rapid
charging (C/2 to C) Ni-MH batteries using the negative
delta voltage charge termination technique. I have studied
the panasonic technical notes on this technique
(www.panasonic.com). I have confirmed the charge profile by
reading the data sheets for Maxim charger IC's
(see www.maxim-ic.com search MAX713). It all seemed straight
forward enough. In fact, I have been using this technique
on Ni-Cd batteries for years. It was just a matter of
adjusting the delta voltage detection and max and min voltage
limits.

However, I am having trouble getting the batteries to produce
a voltage drop. I have tried charging two seperate batteries.
One 3 cell pack. One 6 cell pack. First I tried at C/2. The
battery voltage ramped up nicely but then just leveled off.
No drop was observed on a voltage meter monitoring the process.
I manually terminated the 3 cell charge because I thought
they were getting too hot. When I tried C/2 on the 6 cell pack
the voltage ramped up and leveled as with the 3 cell pack. But
then too my supprise one of the cells in the pack vented before
a drop was detected. At C/2 the max specified time is 3 hours.
Venting occured at 2.25 hour. Just when I was expecting the voltage
to drop.
After discharging the 6 cell pack to 1 volt/cell, I tryed charging
it a C. This time I did get a nice detectable drop, but one
cell vented again.

Any inputs?

As someone else mentioned, you can't solder aluminum.
If you use aluminum - a great choice, by the way - use
stainless steel hardware. If you use regular screws &
nuts they'll rust and corrode. Even zinc plated hardware
will rust in time. Stainless costs more, but is worth
every penny if you want your antenna to last.

Excuse me?.. I merely asked if this was the same chuckee that was around
when I lived down in the detroit area.
By the way, I'm happy to not be living 'down there' and it's wonderful
here in mulliken. Feel free to visit anytime.

[deleted]

I'd be inclined to do this type of experimentation with a single cell
initially, to get a better feel for what is going on. Then use two cells,
and so on. You probably have differences between the cells that is affecting
the voltage measurement.

My experience is that the Ni-MH batteries should have charge stopped
when the voltage stops rising. Do not wait for a drop.
There are a number of chargers that can be set this way.

It is also a good idea to have a temp sensor on the pack to
stop charging if the temperature rises too high.

I am switching to Ni-MH in everything where I use rechargeables.

For items requiring long standby and reliable operation (emergency
lights)
I use lithium primary cells.

My experience with NiMH is limited, but it matches yours. I haven't seen a voltage dip at the end of charge; I have seen the voltage hit a plateau and sit very precisely (according to my Fluke 77 without changing by as much as the 10 mV resolution of the scale I used.

I don't much like the negative-delta method anyway. I've found that older cells, especially weak ones, can get noisy during the charge cycle and make the voltage fluctuate; the fluctuation is easily enough to shut off a delta-V charger, long before the cell or pack is charged.

Have you tried to get an ECG1207 or other equivalent part? I don't find it listed in the NTE catalog, but you can try Questlink.com for the TC5080, but it may be so old that the CMOS part is no longer made. There could be a newer version part which has the same pin outs and would work fine in this application. Packaging may be the greatest problem, however, as the newer part may not come as a dip so you may have to solder on leads. I hope you have steady hands and a microscope. :-)

IIRC, the TC5080 was used in the PLL circuit of the
Sharp 40 channel CR rigs. Some of the CB parts suppliers
might be able to help.

814. Building an RF Switch

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-06-30 18:19:55 UTC
From: amdx <amdx@att.net>
Message-ID: <fZHT8.69110$UT.4792464@bgtnsc05-news.ops.worldnet.att.net>
Source record: 42977

I want to build an RF switch to turn my TV cable signal on and off.
I want to install this were the cable enters the house, and be able to
switch it on and off from inside the house by +5v or +12v.
I'd like to have fairly low attenuation, (I'm already splitting the cable
signal).
I don't know if I need to use diodes, FET switches or relays.
I suspect I may need to build a stripline PC board.
Any suggestions?

Mike

Perhaps he has an illegal cable hookup and needs to shut it off quick if the cable police come around? Around here it is a felony if you are caught with an illegal cable hookup.

If it is a matter of rf getting back into the tv, I find it easier to just shut off the tv while using the hf rig. Though I guess someone might be watching the vcr, rf in thru the cable still shouldn't affect the tv then.
thanks, John.

Sounds almost like the battery is starting to outgas during charging
which causes the noise.

Dana

822. Porblems with VXO, TX birdies

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-01 08:11:53 UTC
From: n2cqr@clix.pt
Message-ID: <3d200e74.765899266@news.clix.pt>
Source record: 42985

I liked the recent VXO thread on QRP-L, and hope I can tap the same sources of wisdom in my effort to resolve a problem I've been having with my 17 meter SSB TX. I first mentioned this problem a couple of months ago in a message entitled "A tale of two Crystals." Put on your thinking caps guys, 'cause this ones a tough one.

Here's the deal: Carrier oscillator at 5.173 to balanced modulator to Crystal filter to NE602 mixer. VXO hetrodyne oscillator (Colpitts, with rock, coil and cap in series).

I have two fundamental crystals from the same manufacturer. One at 23.323 Mhz, the other at 23.303 Mhz. My plan was to use the first for around 18.130 - 18.150 and the other for the lower portion of the 17 meter phone band.

Both rocks work fine in the VXO circuit. I can pull the 23.323 rock about 23 Khz, and the 23.303 rock pulls about 15 khz. Both sound clean when I listen at the 23 mhz freqs. So I don't think the problem is in the VXO.

But when I put the 23.303 rock in the circuit and listen at 18 Mhz, all kinds of spurs and birdies pop up around the operating frequency. They are very close to the op frequency. When I set the RX to a freq in the operating range, and then turn the tuning cap on the TX, instead of the one nice clean signal ("whoop") that I hope to hear, I get multiple signals ("whoop, whoop, whoop"). I can't even tell which one is the strongest. At several points I can hear simultaneous oscillations at freqs within a few hundred cycles.

Strange thing is that this does not happen with the 23.323 rock. That one produces the desired clean signal.

Remember, both rocks sound clean in the VXO -- the problem arises only when the mixer and the rest of the TX circuits are brought in.

Important clue: I tried changing the carrier oscillator rocks. I pulled out the 5176.8 rock (USB) and put in a 5173.5 rock (LSB). Birdies disappeared! "Aha! Bad carrier freq rock!" I thought. I figured I could just pull the "good" carrier freq rock to the desired freq. But when I did so, the birdies returned!

So my conclusion is that somewhere in there energy from the VXO hetrodyne oscillator is interacting with energy from the carrier oscillator to produce the birdies. And it seems that this interaction happens when the VXO is using the 23.303 rock, but not when it uses the 23.323 rock. Does this sound correct?

I've tried reducing the voltage at which the VXO operates. No change.
I've checked the signal level going into the NE602. Correct.

Any theories on what is going on here? Any ideas on possible
solutions? Help! I'm stranded in on the upper portion of 17 phone!

Thanks,

Sure, it's just a way to keep the kids from spending all day
watching Cartoon Network or Nick. If the cable's not working
they might go out and ride their bike, play in the woods, read
a book, maybe even knock another tooth out sword fighting with lengths of
PVC pipe. Mike

P.S. The permenant tooth came in just fine.

> Hi Mike, Can I ask why you are trying to switch it on and off?

hmmmmmm....
The (8 x 5.173) - 23.303 looks suspicious in your application.
But, then, so does:
(8 x 5.173) - 23.323 .....

I think the problem may lie in some 'unique' set(s) of mixing
combinations such as this. That's what I deduce from your
xtal swapping experiments.
Locate an intermod calculation program
(it's application ain't *exactly* for this purpose, but....),
and see what it tells you.

Hm. The noise I refer to usually happens somewhere in the middle of the
charging cycle, long before the cell is significantly above 1.2V with current
applied (I find most NiCD cells go to at least 1.40V before showing the
negative delta-V). I wouldn't have expected outgassing without overcharge.

Hi Bill, This is one of the reasons a spec analyser is quite useful. Not all crystals are 'equal'. I suspect that if you look at that second crystal (23.303) carefully you will find the are parasitic resonances at significant levels. What may be happening is that the osc is not stopping bit jumping to a parasitic resonance and back. This may also explain why it will not pull as far. The main frequency is FMed by the hopping rate so you get a comb of frequencies. The parasitic and the 'hop rate' may be outside the IF bandwith so it may not be heard, (the signal at any one time sound T9) but should show on a sensitive SA.

I had a 1MHz in a BC221 many years ago that had 'modulation' on it !! It was jumping every millsec or so. Of course all these frequencies are present so all the birdies when you use it as het source. It it was an IMD problem you would get it with both rocks. Solution ....get a new rock ...I am afraid.

Cheers de Alan G3NYK

There are hardly any stupid questions on this NG , this one IMO definitely
isn't.

An inductor of 1 mH can be readily wound on a toroid ,provided the toroid
material is suitable for the intended freq. range . For MF or lower HF freqs
a ferrite (antenna) bar as used in a portable medium wave receiver might be
suitable .
Could you be more specific for which freq range you intend using the
inductor ?
Also , is there any RF power involved in the inductor's circuit.
A 1 mH inductor on a former without a ferrous core would mean a fairly large
number of windings.

I recently made 334mh coil, a 42mh coil and a 2.5mh coil.
What frequency range are you working with?

For the 2.5 mh coil I used a pot core 3F3 material with an
A sub L of 6,770.
So... sqrt(2.5/6770)x1000 = 19.21 turns.
As I recall I had to pull a couple of turns off to get the correct
inductance.

You will start as a Technican, provided you pass the test first.
Radio Shack has the ham radio starter kit. Then you need to find out when &
where the next testing session will be in your area. Then bring $6 to the
session, a photo ID, and pencil.
Good luck.

Source record: 42898

Hi,

Can anyone here comment about silk-screen in PCB tools?

I am using Ultiboard for the first time (I have used predecessors) and in this new design I am noticing that some silk-screen on the bottom of my board is "Normal", i. e. readable from the top. Others are reverse, as I would expect.

I have figured out how to reverse the silk-screen that appears "normal", but I just want to be sure I am getting this correct. I don't have a Gerber viewer, and although Ultiboard may have one, right now I don't know what to trust.

Any advice? Most important is the answer on how the silk-screen from the backside should appear.

You have the option of "printing" the top and bottom layers, just run through a couple pieces of paper to see what they look like.

Having done a duplexer myself for a medical radio on UHF, I would advise that this is a non-trivial task. It will require great patience, perseverence and mechanical skill as well as a great deal of research if you have never done one. Good luck. I hope you do it and learn a great deal more than those who only buy appliances and don't dabble.

I would ask firstly if you're sure you want to get into the hobby. It isn't cheap and requires some degree of dedication to complete. If you're gung ho, go for the gold and get a general or better. If you're uncertain, then do what many people do and go for tech or novice. You can have fun as a ham, but let it happen and don't try to force it. It's a hobby! Have fun!

BTW, the FCC just wants you to stay on frequency and not interfer with your neighbor. They don't write or endorse books, etc. I will also say that they are one the best run government agencies (please don't flame me, guys) that I've dealt with, considering their scope and lack of budget.

Disclaimer: I have only dealt with the FCC as a professional RF engineer and have never been an employee. :-)

Happy Trails,

Steve Carlton WB4CZR
Plantation, FL

RF is a pain.

Those are MicroMetal numbers and Amidon does sell them. Try a search
on MicroMetal and you'll find them listed there.

845. Re: Porblems with VXO, TX birdies

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-02 03:40:56 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3d211fcf$0$25598@echo-01.iinet.net.au>
Source record: 42907

It could be a low freq oscillation (eg in the TX final or some other stage)
modulating the signal. If an amp has a sharp response around the frequency
that the oscillation occurs that could be the problem.
You could try:
low freq bypasses (eg 10uF tantalums) in the relevant
places.
Power supply regulation if not already done
Detuning a stage to see if that gets rid of the problem
Substitute another signal source (eg sig gen) for the Xtal
oscillator
Another oscillator circuit or some small L in series with
the crystal

Yeah a spectrum analyser would help.... :-)

You will need to supply other parameters. Required Q and the frequency of interest, current and voltage ratings, for instance. Do you want air core? If you want a ferrous core you will have to specify the value of any steady current through it, as it's the incremental inductance that is usually of interest.

What is the application?

"Clifton T. Sharp Jr." <clifto@clifto.com> wrote in message
news:<3D20A7A6.253A2F25@clifto.com>...

I would like to thank everyone that responded to my note. I have a
couple of comments and then I can share an interesting experience.

Leon. I understand what your saying. That was the approach
I took when I built my first Ni-Cd charger. I charaterized the
charging and discharging charateristics of one cell. Then several.
Verifying, in the process, that there was a big enough negative delta
to detect. Then I built the charger and carefully monitored it until
I was sure it was working. I have been using it for years.
But when it was all said and done, I only verified what I had been
reading about in application notes and articles. So with the Ni-MH,
I thought I would jump right in without all the charaterization.
If I had done it your way, I may have picked up on what I discovered
today.

Michael. The zero dv/dt method is another common charge technique. I
am considering changing the software to use it rather than negative
delta. It will detect the charge completion a little sooner.

Clifton. If your not using negative delta voltage, what charge
method have you settled on?

Dana. I think the noise Clifton was talking about is electical
noise. That is, randon changes in the battery voltage that make the
charger think the battery voltage droped and it is fully charged.
I think your thinking of audio noise. And your correct. I clearly
heard the battery vent before I opened the pack and saw that it had.

After posting my note I called a friend that playes around a lot
with batteries. I did not know if he had been using Ni-MH, but
I gave it a shot. Turns out, he has been using them for R/C airplanes
for about a year. When I explained my problem he said he had heard this
complaint a lot. But he has no problem using the negative delta method
of charge termination. He then said that I must condition a new
battery by trickle charging before I rapid or fast charge it. In fact,
he felt strongly that I should leave it on the trickle charger for a
time equal to a 2 or 3C charge. Once that is done, he said, I would see
a voltage dip. Keep in mind, I tried fast charging the pack twice
with venting occuring each time.
So I trickled charged the pack twice. I only charged it for 24 to 27
hours. Could not bring myself to charge it for as long as he suggested.
Tonight I did a C/2 fast charge with the negative delta voltage charger.
And sure enough I got a clean, sharp drop in the voltage and the charge

terminated right on schedule with no venting. The batteries have been
providing 990 ma-hr after each of the trickle charges. I used 540ma as
the fast charge current. That is a little over C/2 but close enough. The
charge terminated at 2 hours give or take a few minutes. That would
be 10% over the expected charge time (1080/990). Very interesting.
I have a second Ni-MH pack. The place I ordered from messed up
and shipped my order twice (yes, they billed me twice too). So I am
going to try this on the new pack. Nothing I have read about charging
Ni-MH batteries has said anything about conditioning them before
fast charging them.

Whow, whow, whow, Slow up there Steve. I started out about 3 years ago and I will admit that it takes a lot of dedication to get a general and I also agree that getting a general is a good way to go. But, I've spent about $200.00 on my station and I have an excellent HB receiver and a very nice 100W HB transmitter. I'll admit that not every one is going to want to build a totaly 100% HB station but it can be done and it can be done cheeply. But you need to rely heavly on the dedication part. Lots of study and lots of experimenting, much more study than needed for the test that is for sure.

Oh, and to the original poster you can find lots of stuff for the beginner at Radio Shack and you can find lots more for all levels at

http://arrl.org

I got most of my study material for the test from the internet for free and most of my ideas and designs from my local University library's collection of QST magazines and ARRL Radio Amatuer Handbooks. Although the internets seems to have become the defacto source of infomation, one should not ignore the local library.

Good luck and don't forget that a good radio should glow.

No, I'm thinking of electrical noise due to bubbles forming
in the electrolyte, which likely happens long before outgassing
takes place. Bubbles would probably reduce the area of cathode
and anode in contact with electrolyte for a short period of time,
thus creating variations in the electrical characteristics of the
cell. I'm just speculating.

If the cell popped, that indicates it was way over-stressed in
any event.

I'm a little surprised to hear that the battery pack outgassed
twice and still came back to life. Betcha it doesn't last as
many cycles as the other pack.

Interesting about slow-charging for the first cycle. It sort of
makes sense, but I don't really know the internal workings of
these cells. Your experience suggests it's a good idea, though.

yes, but the problem is that it is many turns and too often the result
is poor. What is your requirement?
Found some surplus coils on 1.5mH (Q=660 on 150kHz) and use them as I
don't believe it is easy for me to make anything similar, but you may
study books for Philips cores, believe Amidon doesn't have suitable
cores for inductors in tuned circuits

In just a few seconds download program SOLNOID to design single-layer solenoids. Run immediately. User friendly.

But for a 1 milli-henry air-core coil you will need a lot of turns of fine wire.

Download from website below.

854. 28V suppy ideas

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-02 13:59:01 UTC
From: hamish@cloud.net.au
Message-ID: <3d21b1a5$0$28003$afc38c87@news.optusnet.com.au>
Source record: 42917

Hi all,

I want to build a 28V 20-25A supply to power a ~300W HF amplifier
(which will be my next project). I intend the supply to be linear
due to a complete lack of switch mode experience on my part.

700+ VA transformers seem to be difficult to come by here in
Australia, and they have quite high output voltages too
(starting at 40V), which means a lot of power will be wasted
in the transistors. On the other hand, 500VA transformers are
reasonably priced, available, and come as low as 25-30V out.
However I think I would need two of them, or a 500VA and
a 300VA or similar.

What's the best way to make use of two transformers? I
guess that actually putting them in parallel is out of
the question due to differences in secondary voltage. I
see two other options:

1. Build two 14V 20-25A supplies and put them in series; or
2. Build two 28V 10-12A supplies and put them in parallel.

Option #2 looks better due to the minimum 25V out of a
suitable VA transformer.

Any advice welcome.

thanks,
Hamish

If you are able to find dead/semi-dead UPS'es in <600W
class, you _might_ find transformers with 33-36V(AC)
output. I found my 34VAC/600VA trafo's this way.
But, UPS'es come in so many flavors and colours that your
mileage might vary :)

I have a very nice 2 tube 813 amplifier it is currently tapped for
15-80 meters there is still one spot on the band switch if you wanted
to add 160 or ten meters.
It is a really strong workhorse solid performer. easily does 1 kw on 75
meters can do more ......
It has oil fill caps a really nice heavy duty transformer that is variac
controlled.
She is on wheels so you can move her around. It is not too heavy any
ways. 32" BUD cabinet.
Has 2 - 4 inch muffins fans inside to keep things cool. It has new tubes
i have gone over it and been running it everyday now for about 2 weeks.
everything checks out fine. it runs off 234 volts. Pushing it to the
limit on 75 meters with 130 watts drive she did legal limit .
She runs smooth as a kitten.
Now is the time if you have been looking for a nice floor model amp here
it is. Like i said before all the components are heavy duty military
spec. Take a look at surplus sales of nebraska and check out the prices
on some of the components....
I would like to sell it or maybe trade for some type of hf gear of equal
value
, radios , amps what do you have? I am asking 650.00 for this beautiful
amp.
Oh you ask why would i sell it. I have several other amp projects on the
work bench right now and really need to make room.
here is a link for a pic. If it does not work email me and i have more pics.
this is a pic up only item in Taylorsville North Carolina....about 60
miles north of Charlotte.
thanks for taking the time to check it out.

Source record: 42922

Hi Hamish,

I have seen a number of published designs that use your suggestion to get over transformer limitations and either method (parallel the transformers or parallel the DC supplies) will work. If you are paralleling the supplies you can do it either before or after any stabilisation depending what components you have available. There is no need to limit yourself to 2 transformers etc. If you can get three 8A transformers for less than two 12A ones then use 3 in parallel. The key is to use identical transformers or supplies, that way you have a better chance of avoiding problems.

As far as transformer voltage is concerned you need to take into account the various losses in rectifiers (0.7v for biphase, 1.4v for a bridge) etc and leave enough voltage across the stabiliser circuit to ensure that it works. A good rule of thumb is that a 13.8v PSU requires a 17v transformer. That suggests that, for a 28v DC output, you are going to want a transformer with an output of not less than 31v at its rated load.

I hope that helps.

Regards,
Hugh

==========
Hamish , You might wish to consider using power MOSFETS instead of bi-polar
pass transistors.
Their 'on' resistance is in the milliOhms range ,hence they offer a low
voltage drop at high current.

The two crystals are almost exactly a 9:2 frequency ratio, so the
oscillators may be pulling each other. To test this, run only the
oscillator stages. Listen around the two oscillator frequencues, to
see if either of them is unstable without the high level RF.

If that works properly, try the same test with increasing amounts of
power (perhaps adding one stage of RF amplification at a time). If the
problem is power dependent, you probably have RF feedback. You'll need
to find the leakage path and correct it.

Good luck!

You need a load balancing circuit to get the parallel power supplies working properly. Otherwise, the one with a slightly higher voltage will run up to its current limit while the lower voltage unit loafs. There are commercial ICs to do this job, or you can roll your own with a couple of spare op-amps if you prefer.

Total heat will probably be lower with the 28V supplies, instead of series 14V units. You avoid having the extra diode drops, current sense resistors, etc. being in series.

Plan on using transformer with rated VA about two times the rectified DC power--the power factor of capacitor input filters is pretty poor. The factor of two is based on my experience with units around 750VA rating.

Well, instead of using a regular EI transformer's primary, why not use a regular EI transformer and put the AC line source into the secondary, i.e. making the secondary winding the primary. The VA rating of an old-fashioned color TV transformer, unfortunately, isn't going to carry this load.

As a second suggestion, if you have the nerve, consider building an off-line switcher. The a.c. line is rectified, filtered and interrupted via a chip like the International Rectifier IRIS series to drive a step-down transfomer. You can use outboard HEXFET's to drive more current through the transformer. Feedback to the IRIS chip can be via a secondary winding, or opto-coupler. International has an application note on winding transformers for their IRIS PWM chips on their website www.irf.com with references to various transformer and core suppliers. To be honest, I have built a number of switching supplies, but have never tempted fate with an "off-line" switcher.

Thirdly, I think that it was January 2000 when QST had a high power switcher. I'll have to go take a look in the dungeon.

Does anyone know about "burb charging"? This is a short discharge before regular charge. It gets rid of the bubbles which impede charging. It works. I don't know about whether or not it's patented. I don't want to stomp on someone's parade if it is.

BTW, why do people care about using a radio with its battery charging? When I was doing full time engineering, this was a concern. Why? I don't know. I just made the system work even when people were using the xcvr in the charger with a dead battery using a remote speaker/mike wrapped around

the helical antenna and that is no lie. :-)

If the transformers are not identical, there might be some problems.

One way to connect transformers in parallel is to put some inductance between the hot ends of the transformer secondaries. A third transformer, with a high current, low voltage (1-5 V) centre tapped secondary might be useful. Connect the hot ends of the main transformer secondaries to each end of the secondary at the third transformer. Take the output from the centre tap of that secondary, the primary of the third transformer is unused.

An other method would be to use separate transformers and rectifiers and a common capacitor and regulator. Small resistors or preferably small inductances would be needed between each rectifier and the capacitor.

If you have 3 phase mains available at your site, why not use a 3 phase transformer or tree single phase transformers connected in a star or in a delta. The size of the capacitor can be greatly reduced and still the voltage fluctuates very little during the AC cycle, thus the required voltage drop across the series regulator can be greatly reduced, greatly reducing power dissipation in the regulator. You might even run the transmitter directly from the capacitor voltage.

Three transformers with maybe 15 V secondaries should be able to produce about 29 Vdc with 1.25 Vrms ripple _without_ a capacitor. Other rectifier configurations with 25-30 V centre tapped transformers should also be able to generate suitable DC voltages.

The truth is when making a homebrew project it is not allways possible to find a ready made transformer at the specs you want (Murphy's law) the thing I do in these situation is order a customized transformer from a transformer maker to the specs I need. It mite be a bit more expencesive but in the end there is no compromising with the quality of the outcome.Find a transformer maker in Australia and order one to the specs you need (you will be happy with the results)

The 1mH coil is a choke. It can be anywhere between 0.5 and 1.5 mH.

Construction is 4 or 5 separate pi-wound coils along a dowel, 3" long by
1/2" diameter.

Problem is high voltage between turns. Do not attempt to make one yourself.
Buy one.

What would the load balancing circuit look like, roughly?

Typically these linear designs seem to have a few pass transistors
in parallel with the emitters connected together via a small
series resistor per transistor. I assume this compensates
for different gains in the transistors. Is it acceptable to
add additional pass transistors with a seperate power supply
and simply connect their emitters in the same way?

Thanks everyone for the suggestions. I'm also wondering whether
I should go for 50V DC instead; I want to power a ~300W HF
solid state amp, and it looks like 50V might be a better
choice. More options for upgrading to 600W later too.

Regards,
Hamish

Someone else suggested MOSFETS. There are a number of cheap MOSFETS that would get you into the 300-600 watt range off a 12 volt supply. Most will operate up in the 60 volt range or higher, but a 60 or 100 amp MOSFET would give you plenty of power in push-pull even with 12 volts. In any event, it certainly gives you more flexibility in the transformer department.

I suspect that bipolars in the neighborhood you are thinking aren't going to come cheap. 60 amp MOSFETS fast enough for HF can be had for just over a buck a piece this side of the Pacific, they can't be all that much more expensive in VK land.

Of course, whenever you are talking about 600 watts from a pair of transistors in linear service, getting the heat away from those puppies will be quite a project in itself.

..

Hamish,
If you don't want to bother with the design of a SMPS, and still want avoid huge power waste, you have another choice : a mixed design.

Have your main transformer/bridge/cap bring you down to what ever you want or can (above the 28V target), then have a buck stepdown switcher that will get you to the targetted 28V.
Buck structure is simple, don't have to manage high voltage, transformer... and other "weird" things.
You will very easily find the components, and a well designed one will be robust and "happily welcome almost any abuse" you can think of.
For a homebrew regulated high power supply this may be the best heat/size/cost/time/efficiency... ratio.

Fred.

No, milliOhms RDson is totally useless here since the transistor is working
in its linear region.

Be careful with these levels of voltage/current as bipolars (second
breakdown) are at least a bit susceptible.
And you can't simply parallel mosfets to achieve the required rated power :
in linear mode they have a big thermal positive feedback that make mandatory
to use some balancing source resistors, which is not welcomed with those
high currents.

Fred.

>Bill,
> Interesting problem. Your troubleshooting ideas are very good.
>I noticed that your VXO is very close to 4.5 times the I.F. Am trying
>to work out what interactions might be happening...
>9X 5.174 = 46.566
>2X 23.3 = 46.6

Glen: That's got to be it. Here's the confirmation:
The carrier oscillator is actually running at 5.176 (producing LSB
which
turns into USB after the mixer).
5.176 x 9 46.584
With the 23.303 rock, the VXO runs from 23.306 - 23.291
23.291 x 2 46.582

Further confirmation comes from the observation that the problem gets
worse
as I go lower in freq, as I get closer to 23.291 (and as I said, this
is not
a problem with the higher freq 23.323 rock).

So I'm almost certain this is a 9x 2x interaction problem. Now I have
to
find out where it is happening and how to surpress it. Last night I
tried a
series 46.582 LC trap at the output of the VXO. Didn't have any
effect.
Tonight I'll try shutting down RF amp stages to see where the birdies
stop
singing. Stay tuned!

Whoa, Whoa, Whoa, slow up there, Rick.

Steve is exactly on target. You are an exception - a
very rare exception. MOST new hams will not be able
to put together a station that includes an excellent HF
receiver and a very nice 100W HF transmitter for 200 bucks,
even buying an old transceiver.

Most new hams won't be able to build an excellent receiver,
at any price. Heck, most new hams can't even build a
100 W transmitter. There are a few exceptions, of course. You
are one of them.

You are right on target with dedication. If one is truly
interested, he can develop the skill and knowledge to
brew a nice station, often starting with single band
QRP, CW and working up from there. But MOST hams (not
restricting it to newcomers) cannot build an excellent
receiver, unless its from a kit. A very small percentage
have the experience and expertise to do that.

More buffering. An attenuator followed by a gain stage that compensates
for the attenuator's loss is a great way to improve load isolation.

I don't understand this suggestion.

In a linear regulator with bipolar transistors, the transistors are used
to drop a certain amount of voltage at the desired current. They must
dissipate that V*I, which usually requires a substantial heat sink. If
a MOSFET is called upon to do the same regulation, it also has to
dissipate the same V*I, doesn't it?

MOSFET's shine when you don't want a voltage drop. The low RdsON that
some provide gives you both low voltage drop (I*RdsON) and low power
dissipation (I*I*RdsON). But, in a power supply, how can you use that
to advantage unless you're pulsing the MOSFET's? And wouldn't doing
that then require HUGE capacitors to smooth things out?

You might call it "manual negative delta-V". I hook it up to a current source and watch the voltmeter for the delta-V trend at the end. Pain in the rear, but it charges packs that won't charge otherwise.

888. 2.4GHz amplification

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-03 21:56:57 UTC
From: kd6ozk@hotmail.com
Message-ID: <e2ff41a.0207031356.7e4a7b12@posting.google.com>
Source record: 42851

Hi all. I've been reading a discussion in a computer security mailing list, and the current thread surrounds wireless LAN cards. These puppies run at 2.4GHz and usually are limited to a few hundred feet because of antenna design and power output.

And it occurred to me that it may be possible to amplify the signals and extend the range. I don't know how legal a 2.4GHz TX amp would be, but I assume an RX amp would be allowed. I also assume that using a dish or a good hi-gain yagi could extend a LOS connection to a kilometer or more.

It also occurred that the Amateur Radio community might be the best resource for this side of the discussion. Alas I have very little knowledge WRT microwave amplification (or much other amplification, for that matter), so I am asking of the readers here for any thoughts.

I don't need any details, but they are welcome. I still have my own research to do, such as checking regulations that cover the band, but if anyone has any thoughts or is aware of any existing equipment, I would certainly appreciate hearing from you. Emails are fine, I will summarize.

Thanks,
Larry

Does anyone here have experience with building a 2 meter FM transceiver (or transmitter or receiver only) based on the MC3362 and/or MC2833 chips manufactured by Motorola ?

According to the specs of these IC's it should be possible but I can only find designs for 10 to 80 meters or so.

Any designs and/or hints would be very appreciated as I'm trying to establish the feasibility of such an undertaking.

Kelvin,

I always like hearing about persons interested in a great hobby. There are hundreds of things within amateur radio that you can do. Like most of the responses on the newsgroup, you probably will look at obtaining a Technician class license first.

The ARRL: www.arrl.org has a wealth of information for newcomers to the hobby. It will probably be overwhelming as it was for me when I first started studying for my license over 10 years ago.

You won't find any books "sanctioned" or "approved" by the FCC because that is not in their mandate. You can freely download the FCC question pool from a number of websites. I would recommend using a study guide though, as it covers more than just the FCC regulations.

I used the "Now you're talking" text from ARRL. I'm buying a copy for my sister who has expressed an interest lately. It takes you through all you need to know including operating procedures, all kinds of background information on the hobby as well as the "why's" behind most of the regulations put forth by the FCC. There is some wrote memorization (ie: frequency limits & power levels) but most of the questions follow common sense principals. There is some electrical theory that is very basic and easy to learn and understand, but not a lot of complex concepts.

I studied for three weeks while in college (studying for about 30 minutes/day) and passed the test with a perfect score. It isn't hard to pass the test, but you can't just walk in and expect to pass.

I then had to wait about 6 weeks for my license to come in the mail. They didn't have the websites where you can look up your license back then. I saved up and purchased a dual-band HT. Still have that HT and use it regularly. I also have a dual-band mobile.

I originally didn't think I'd want to learn or use morse code and it isn't necessary for the Technician class license, but after 10 years in the hobby, and looking at renewing my license, I decided to upgrade to General. I used the ARRL morse code CD's and General Class Study Guide. This time I spent almost 3 months working on the code and theory. Passed my test on the first try- even copied well over 1 minute of code!

I saved up and purchased a new rig for HF and now am starting to actually use CW on the air. It's a lot of fun and very satisfying!

I hope you take the little time needed to pass your Technician class license, you won't regret it!

Please feel free to contact me via e-mail if you have any additional questions.

Sincerely,
Matthew Hodges, N8UVF

Go ahead and look me up at: www.qrz.com entering my callsign in the box in the upper left corner of the page.

I was referring to the transistors in the amp, not the supply.

By having the choice of lots of amps, one could come up with a 300 or 600 W amp with a different voltage supply. Originally, Hamish was struggling with the availability of transformers to come up with the 28 volts he needed to get 300 watts out of an amp based on bipolars. By choosing MOSFETS, high current RF transistors can be had pretty cheap. It's tougher to come up with bipolars for that service you can afford. I wasn't so much suggesting MOSFETS for the supply, the transformer problem remains if you still need 28 volts.

If HV is an issue, I would recommend a ceramic or glass core and an application of dope to passivate the surface and windings.

> suppose 1MH is much more than you need, 80uH would be self resonnant
> around 80m(?)

I agree with the "?" above. SRF is highly dependent on construction in any value's case. The low frequency value of inductance is not important, but it would be nice if you are near SRF without crossover. For example, it does no good if the value at 1 MHz is 1.5 mH if the impedance at the operating frequency is 20 ohms of capacitive reactance and 20 ohms of resistance. That's why RF is a pain and requires loads of test equipment which is beyond the budget of most hams. I hope your project comes out well, no matter what. Please keep trying and have fun while learning.

Actually a 50 V power supply (or 48 volt) is easier. Telecom industry
uses - 48 VDC so the surplus market should have a number of items available.

The power transformer is standard 2:1 based on 120 VAC to 60 VAC, if you are
running 240 VAC, then it is a 4:1 drop - but still a number of options
available in the market.

My comment assumed you were making two completely separate power supplies and hooking them at the output, in series or parallel. I'm sorry if that interpretation was wrong!

The most common load balancing circuit works by having a load control wire between the two units. Each supply drives that line with a voltage porportional to load current. The driver has a series diode, so the highest vote (current) determines the signal level. Then both supplies compare that signal to their own load, creating an "load share error" signal. The error signal increases the output voltage of the low current unit to reduce the error, which balances the current. The Unitrode/Texas Instruments) UC3907 (or is it 3906?) performs this function, and their data sheet describes the operation much better than I can!

But all this assumes two complete stand-alone supplies (which is commercial thinking, not amateur!). Plan "B" puts all the parts into one chassis. Each transformer has its own rectifier, filter, and pass transistors. The transistors have their own emitter ballast resistors, as you mentioned. Then you drive all the bases (gates) with the same control IC, and you have nice load balance with a much simpler circuit. You just need a bigger, stronger box to hold it all ;<)

Good luck with your amplifier project,

Since I don't have the capabilities of creating silk screens, what is there that I can use for small letering on a project? I also have some existing gear that has damaged silk screen lettering that I want to repair. Any ideas on how to make this happen? Is there a source for dry transfers with a variety of sizes and fonts? What do you homebrew experts suggest?

Thanks

The MC3362 dual-conversion receiver IC should be useable since the data sheet says it's good to 200MHz. Maybe there's an application note that provides more information than the data sheet provides. I have a vague memory of seeing a 2M FM receiver using an IC in QST, an issue that I only saw in passing, and I suspect it used either that IC, or one of Motorola's similar ones.

I've never quite understood the purpose of the MC2833 FM transmitter IC. It makes such a simple transmitter, low power and lacking much for multipliers, that by the time all the external circuitry is in place, the active components to provide the same functions aren't going to complicate things much. There was an article in QST maybe 1988 or so (?) about the IC, but it was hardly a construction article. The data sheet shows components for a 2M transmitter, but if you look closely, it uses a 12MHz crystal and then 144MHz out, but with three stages it sure looks messy.

Paralleling of secondaries shouldn't be automatically be ruled out.
Certainly most Aus manufs I have dealt with in years past have wound
their product to a set turns ratio. Apart from small variations
resulting from materials, this should cause insignificant circulating
current. It might pay to contact a supplier to find out whether you
can return units for exchange if they produce an unacceptable level of
Icirc when //ed. That way you could suck it and see.

Also - BTW - Transworld produced a kilowatt HF linear using a 12V
rail. Was even type approved here in oz at the 500W level which was
all that the user could get the authorities to permit.
It isn't impossible to work it at 12V.

Don't put two DC supplies in series, or parallel, unless
you do it at the output of the bridges. If you series
them, both need to be capable of 25 amps.

I'd use 2 28 V 500VA transformers, each feeding its own
bridge rectifier. Put the output of the bridges in
parallel. Your pass transistors will have to dissipate
close to 250 watts at full load (25 amps). I'd use
4 or 5 2N3055's (because I have a bunch of them) or other
bipolar than can handle 100+ watts each, on a big heat

sink with a muffin fan. An LM317 in collector wraparound will give you a nice variable supply. You'll need equalizing resistors in the emitter of each transistor - about .1 ohms at 5 watts each.

That's the design I used for a supply I made. I had a single 10 amp 36 volt transformer to use in a 13.8 volt 10 amp supply for a 2 meter rig. My supply has to dissipate close to 350 watts worst case, but I had all the parts on hand, except for the 7812. (It is also on a heat sink. The 7812 takes the place of the LM 317 in my supply, because I wanted a fixed voltage. I added 3 diodes to bring it to ~ 13.8)

Micro-Mark (www.micromark.com) makes clear water slide decal
paper that you can print on with a laser printer. You can then cut out
the names, soak them in water for a few seconds, then slide them onto
your panel. When they are dry, coat the panel with clear Krylon.
I've lettered panels successfully with it. It's a little bit flimsy but
practice on a scrap panel first.

It is a little tricky. Try this:
1. Go to www.motorola.com
2. Click on "Semiconductors"
3. Click on "Documentation Library"
4. Click on "Literature Distribution Center Archived Documents"
5. Enter "AN980" for the document number window and click "Search"
6. Click on "AD980/D" in tne returned results.
7. Click on the second "AD980/D" of the returned results of the second search.
That should get you an Adobe pdf version of the data sheet.

You also might try:
http://merchant.hibbertco.com/fs22/deact/fs12/motorola/AN980_REV0.PDF
to get you there directly.

We had a demo at our local Experimental Aircraft Association meeting of using the silk screen process to mark aluminum instrument panels. The presenter said you can get silk screen kits at hobby shops, etc. It worked out really well. You might try making your own silk screens! Good luck with the project!

I use Datak dry transfer labels. The label contains a paint that transferres to the panel when you rub on it with the tip of a pen. You can get them with common electronic words. I get them from a local supplier but I notice that they are listed in the catalog for Antique Electronic Supply (http://www.tubesandmore.com)

Hi Bob,

I recently used an ink jet decal system to replace a Gonset GR-212 logo.
The results are fabulous. Because the clear substrate is so thin, it is
visible only under perfect lighting conditions. I was not aware of the
laser decal system- but will definitely pick this up too. Thanks for the
tip.
For those using these systems- spend the time to match the original Font
and size- Drake, Gonset and probably all the rest used common fonts, even
back then.

I have also done the custom silk screen- but would not recommend it unless
the entire panel needs redoing.

MMICs are the easiest way to get some more gain for the Rx.

I don't want to sound like a party pooper, but operation at higher xmt
levels is not a legal option. Even improving the antenna efficiency may
not be legal if the ERP level is limited by requirements. It is legal to
improve your path loss by placement of devices, etc. with the obvious
conclusion being that the lower the path loss, the better the reception
and so on.

Happy trails,

Steve Carlton WB4CZR
Plantation, FL.

That sounds interesting Fred.. any suggestions for locating
a sample design (app notes etc)?

I assume the main transformer is still a large VA unit so is
there much advantage - just less heat dissipation?

Yes, that's one option. Alternatively it seems it might be better
to join them together after the bridge rectifiers. (One bridge
rectifier per transformer, joined at the outputs.)
Or just supply the transistors off different supplies, as you
suggest below:

> one chassis. Each transformer has its own rectifier, filter, and pass
> transistors. The transistors have their own emitter ballast resistors,

I think this is do-able but the return won't justify the investment for most systems (apologies for the management/techno babbledygook).

According to the last numbers I saw, the noise figures and gains of these systems is already not bad. They could be better, but not a lot. A dish or high-gain yagi for 2.4 gigs may be a modest size to an amateur radio operator, but it probably looks huge to computer folks, and feeding signal back and forth between the antenna and computer would be a substantial increase in complexity.

There may be more-clever approaches, but I'd imagine something like this:

You'd want a nice low-loss feedline (translate: large diameter) between the antenna and the LAN card. You'll need additional T/R switching for the preamp. Or you'll have to put the LAN card at the antenna and run the computer bus to it (tell the computer folks that one!). Not being standard office decor, you probably need to put the antenna on the roof, and be careful to point it accurately. While you're at it, get rid of any other buildings between your remote site and the server.

This sort of thing is sometimes done (not the part about the buildings :-) for a wide area network (WAN) to link the servers of smaller LAN's, but I expect there's not much demand for the LAN's themselves.

Of course, for amateur radio I've done lots of things just for the fun of it that were of questionable practical value.

... Rich

Depending upon you radio, the silk screen may already exist

Johnson's and HQ-180
http://w4pnt.8k.com/refinishing.htm

Heath, Collins, Hallicrafters, Johnson, others
http://www.nctotalelectronics.com/

MAKING HAMMERTONE FINISH HAMMER

Years ago, sheet metal was often supplied in coils and if the smith did not have a uncoiler and straightening roll press (expensive!) he "planished" the metal flat with a planishing hammer. The planishing hammer has a very slight dome shape to the head. The metal was worked from the center to the outside edges in overlapping passes. Later, hammertone finishes were developed to simulate this look. Getting a good hammertone finish is just about as easy as painting with any aerosol type finish. It is important that certain rules be observed:

1.. Surface must be clean and dry. Clean means no rust, oil, grease or fingerprints.
2.. Be sure that the temperature of the paint can and the surface to be painted is between 70 and 90 degrees F.
3.. Spray with even strokes at a distance of 14 to 16 inches. Spray lightly horizontally then again vertically. Dries in a few minutes, depending upon temperature.

NOTE: When the temperature of the can is appropriate, shake can at least one minute and occasionally during use, making sure the ball agitator in the can is moving freely.

MAKING WRINKLE FINISH WRINKLE

Getting a good wrinkle finish is just about as easy as painting with any aerosol type finish. It is important that certain rules be observed:

1.. Surface must be clean and dry. Clean means no oil, grease or fingerprints.
2.. Be sure that the temperature of the paint can and the surface to be painted is between 70 and 90 degrees F.
3.. Spray with even strokes at a distance of 8 to 12 inches. Apply a fairly heavy coat.
4.. Spray a second coat approximately 3 minutes after the first, also fairly heavy.
5.. The wrinkling will appear gradually, requiring about 12 hours at room temperature to completely develop.

6.. Experience seems to indicate that a better finish is developed when sprayed onto bare metal.

NOTE: When the temperature of the can is appropriate, shake can at least one minute and occasionally during use.

Yes, heat will be greatly reduced and almost constant vs input voltage. So
you have a greatest flexibility for choosing your transformer. Also (ex.)
56V input / 28V output mean your post transformer bridge/cap requirements
are reduced the by the same ratio (but be reasonable).
This also holds for size.
Another good point for homebrewing is that it can be virtually
indestructible. (short circuit protection - small output cap so low energy
stored at output and low damage on accidental short circuit)
And last, but not least, mosfets are very cheap. Heat sinks can't rival at
all.

Efficiency might also be a concern (at least in summer) and a 85/90%
efficiency versus maybe 50% for a linear psu can be welcomed at the 0.5/1 Kw
level if all the stuff is in the room.

For appnotes search major mosfets & smps controler manufacturers sites for
"step down" or "buck" SMPS (this is the right SMPS structure to go with).
You'll find plenty of.
Onsemi / Irf / LT / ST / TI-Unitrode / Fairchild / ...

Anyone know where I can get custom made crystals in the UK. HC49 size ideally but other sizes not much of a problem. Looking for Top band QRP freqs. Any suggestions on what spot freqs. to use phone and CW also welcome. I've found kanga at http://www.kanga.demon.co.uk/crystals.htm but they only do one at 1.8432 and the postage and packing is a bit silly just for something that only costs a pound.

Ideally looking at a number of them i.e. a couple for CW and a couple for phone.

Ideally looking for a website with an order form.

(also looking for same for 80m, though I have one at 3.579 already)

Hello John

I used two ceramic filters in cascade for each bandwidth.
That would have place the "jaggies" well over 80 dB down compared
to a single filter. If the "jaggies" responses were unique to each filter
even better suppression might be had when a cascaded arrangement.
That was something I never verified, however...
The filters were harmonic-mode Murata ceramic filters (New Narrow-Band
Ceramic Filters From Murata-- Littlefield, CommQuarterly, Summer 1994.)

The log amp/detector was a AD606. No abnomolies showed on the
slopes over the 75 dB display range. This was a log IF project
for the Fall 1996 issue of Communications Quarterly Mag.

923. Re: Homebrew RC equipment on ham bands?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-04 20:27:04 UTC
From: Chris Boone <Cboone@earthlink.net>
Message-ID: <3D24B042.4E156404@earthlink.net>
Source record: 42886

You are correct......FCC regs do not specify a band or freqs...
ANY freq that the type of emissions are allowed is legal for RC...
Note that the 6mtr freqs have changed to the 50.8-50.98 region...
and now are 20 kHz spaced......you would probably have to upgrade
your rcvr to a new model.....and then have the xmtr correctly set to
deviation, etc....AMA rules for planes specify that you MUST use
20 kHz equip on the 50MHz range and they are discouraging use of
the old 53 MHz channels...

I would not use 2mtrs for this.....other than saying that, its
hard to recommend a band OTHER than 50 MHz.....220 and 420-450
are crowded in metro areas (well most of them anyway...Houston
is somewhat devoid of activity on a lot of freqs! :)
1.2 GHz may be the best bet but stay away from ATV used channels
as well as FM rptrs and weak signal/sat operations...(does that
leave any room at all??) I would HIGHLY recommend DIGITAL over
analog at any time!!

If you are out in the boonies, 1.2Ghz or 220 may be ok...

BTW you CAN run more power than 1watt on RC PROVIDED you legally
ID the station...the 1watt and below rule is there to exempt you
from the ID required...but your callsign, etc must still be on
the xmtr..

Anyone want an HT32A manual to go with their HT32A? Just pay me postage costs and it's yours. Downside: I have to send from UK, and front, back and circuit pages disconnected from main body. But, otherwise fine. First posted response secures. Postage to US would be about $3.00. Three one dollar bills would be okay.

If you go to Cisco's website (www.cisco.com), then downloads, then WLAN you will be able to download a 1 page excel spreadsheet that calculates all relevant figures, gains, suitable antenna, cable lengths etc... it will also tell you if your virtual config is against any regulations! :-)

It's branded Cisco but it's generic stuff. It will only model around Cisco antennae though, but again the specs can be found in the manual appendix for several of the WLAN cards. None of this kit as actually made by Cisco.....

I successfully bridged (at 11Mbs) two LAN's (Line of sight) at a distance of 1.3 Km in central London! Your security concerns are well founded though, doesn't take much at all......

If you're researching I'd check out PRISM and Lucent Wi-Fi cards, as between that pair about 70% of the WLAN card sales can be found, Therefore they have a better developed product and generally more info is kicking about on these cards.

Have fun,

Si.

Part 15 wireless networking devices at 2.4GHz are allowed a remarkably
large amount of transmit power and antenna gain; I personally have experience
with a system based on conventional Lucent 802.11b cards combined with
high-gain antennas and amplifiers that achieves a solid 11Mbps link
over a distance of 12 miles. If you read Part 15 very carefully with
respect to 802.11b point-to-point operation, you can run up to +30dBm
of transmit power into a +6dBi antenna; above this, the maximum transmit
power is folded back at the rate of 1dBm/3dB antenna gain. With a +24dB
antenn system, you can run +24dBm of transmit power, for example, and this
is more than adequate to cover 20km in a point-to-point configuration.

While your caution regarding legal restrictions is reasonable, you're
apparently unaware that use of amplifiers and high-gain antennas for
Part 15 wireless networking devices is certainly legal.

I just want to point out that isn't always true outside the US.

In the UK, EIPR is 100mW (20dBm) . The reg. is ETSI 300-328. Source:
<http://consume.net/twiki/bin/view/Main/LegalLimit>. I believe the
rest of Europe may be similar.

This limit applies to the whole radio setup, from the tranceiver card
to the antenna.

EIRP is 'Effective Isotropic Radiated Power' which means it is
measured, in any direction, as if it were coming from a true isotropic
radiator i.e. in all directions at the same level. In other words you
are not allowed to radiate in ANY direction at a level greater than
you would have from an isotropic radiator, so by definition is ISN'T
different if you have a directional antenna.

For a Canadian perceptive, it gets fun. See BC Wireless's web site
<http://bcwireless.net/wiki-moinmoin/moin.cgi/Regulatory>.
Industry Canada documents: RSS-210 and RSS-139
1W (+30dBm) from the transmitter, 4W (+36dBm) E(I)RP, channels 1-8
indoors only without a license, channels 9-14 may be used outdoors
without a license, and Radio Comm Regulations prohibits the average
person from manufacturing or modifying transmission equipment.*

*] IMO if you built or modified the transmiter and held a Canadian advanced qualifications amateur radio license I guess you could operate it, but as amateur radio gear, i.e. amateur power restrictions, no encryption, no WEP, and with callsign IDing every 15 minutes to other licensed amateurs.

I hope to setup some wide area networking using 802.11 hopefully soon, glad to hear of your successful use of it over a long path.

Dana

I'm not an expert on this particular band, but those numbers above are surprising to me for an unlicensed band. Besides that, just from an EME aspect, I don't think that I would want to be sitting in this strong a field of microwave energy. I guess it's okay if you remote the antenna, but then you have line losses to worry about unless you want to complicate the system more with data lines out to a remoted xcvr. If you have an amateur licence then you could just set up your own MDS on one end and let your buddy at the other end with an amateur licence set up his. This would solve the whole problem. Don't they still allow wideband at 2.3 GHz. ? I don't keep up with these things now.

My experience is in CT2 and Bluetooth (to some degree). I've also done alot of work at low, mid, and high bands as well as UHF for public safety for a company whose name starts with an M. ;-)

No matter. RF is a pain.

That'd be about the only valid reason for using 3055's.
These transistors, often listed for linear PSU duty, have abysmal HFE
at any half-decent current. For a project like Hamish is planning, a
type with higher gain and still a decent power rating would be
preferred IMOE.

Simple.
Get two 300W computer supplies. Modify the regulator to output 14V on all
12V lines. Combine the12V lines on each supply. A 300W computer supply
will easily give 20A+ of current. Combine the two supplies to yeild 28V.
You will need a couple of power resistors across the 5V line of each supply
to initiate regulation. Approx 5 ohms 20W. Yes they are switching supplies
and if using with HF you'll want to put a few ferrite cores on the voltage
lines to eleiminate the switching noise.

Have a look at the latest revision of Part 15, specifically
15.247:

http://www.fcc.gov/oet/info/rules/part15/part15_5_30_02.pdf

Frankly, given the relatively large amount of off-the-shelf
11Mbps equipment available (PC-Cards, access points, mast-mounted
amplifiers, and antennas), I'm surprised that hams aren't a little
more excited about the stuff. Remember the wailing and gnashing
of teeth trying to get from 1200 baud AFSK to 9600 baud FSK that
ultimately stalled packet long enough for the Internet to kill it?
Here's wireless Ethernet speeds out of the box, and amateur
radio experience, aligning antennas and so on, is very valuable.

> My experience is in CT2 and Bluetooth (to some degree). I've also done

Ahhh... Bluetooth - that's *sure* taking some time to gain
traction... the key there will be a $2 single-chip silicon
implementation... not quite here yet, still, though there keep
being promising developments.

I do believe you and that you're right. It's just an unusual regulation compared to others that I've dealt with in the past. I still don't like sitting next to a microwave xtmr at those levels. Next thing you know, they will allow pulse modulation at low frequencies on this. Then I'll have to move to the next county or into a missle silo in Hermosa, SD. :-)

Read Appendix A of
http://www.linear.com/pub/document.html?pub_type=app&document=65
which is an excellent introduction into the different charge termination
methods.

Have built a charger based on ICS1702 made by http://www.galaxypower.com/
Get the datasheet http://www.galaxypower.com/organization/ics1702.PDF and
read about their charge termination. Never ever had a problem with this
charger (batteries getting hot etc.). Am operating at C/2.

http://www.spontaflex.freeserve.co.uk/

The Ingenious circuits of Sir Douglas Hall.

Updated the list of component suppliers and added a letter from
Sir Douglas giving a brief history of his radio construction.

Still have lots of articles to add but have used up all the webspace allowed
by freeserve.
Tried condensing the jpegs even more to gain some space but quality
deteriorated too much.
Any suggestiond to free up some space?
I'v been told adobe acrobat format would help but this is the one program I
hate using.

Cheers
Geoff

A very interesting site, Geoff! Many thanks for putting it up.

Why not just open another Freeserve "pay-as-you-go" account (or
indeed, one with any "free" ISP), complete with another allocation of
web space, and link to pages on it from your main site.

Better still, you could just use a subdirectory at the secondary site
as a location for the graphics files, and point to them at the
secondary URL in your html code. Many of the graphics and audio files
on my main BT Internet Web pages are, in reality, located in a
subdirectory on a Virgin Net web server, but this is completely
transparent to the user. This frees up webspace on the main server
for additional html files.

If you want some examples of how to code this, just drop me an email.

(snip)

Typical peasea PSU's have a poomteenth of an amp on -5 and -12, and
the remainder of the total wattage is split 50:50 between +5 and +12.
So a 300W unit would be good for ~12.5A on +12 rail. Of course, your
unit(s) could be different.

The "VHF/UHF manual" by G.R. Jessop, G6JP, published by the RSGB (ISBN
0 900612 92 4) contains some tube based receiver circuits (not
complete receiver schematics) at least in the 4th edition (1983, with
multiple reprints at least up to the 1990's). I guess the older
editions might contain more tube circuits.

>or will this be pretty difficult?

Building an VHF/UHF receiver is not very hard with modern components,
such as MMICs, with low and constant impedances and plenty of gain.

However, if you insist of building the VHF/UHF receiver with tubes,
there are going to be problems with the stray capacitances and
generally quite high impedance levels.

One way to implement the UHF preamplifier is to use grounded grid
triodes, which effectively isolates the input from the output.
Nuvistors and other very small tubes are often used with flexible
leads directly soldered to the circuit to reduce the stray
capacitances. The real problem is were to find such tubes, since they
have not been used for decades in new designs.

The noise figure of tube preamplifiers were generally quite lousy
compared to modern solid state devices and the oscillator stability
was not at all good.

If you are interested in building tube receivers, I would suggest
building a 0-30 or 0-100 MHz tube receiver and building a solid state
down converter from the frequency range of interest. A crystal
oscillator followed by 1-3 frequency multiplier stages will give a
high stability and using a GaAs-Fet as the UHF preamplifier will
enable a very low _system_ noise figure.

When looking at old VHF/UHF receiver designs, you should remember that
these were designed in the days when there was only a few signals on
VHF/UHF and the signal levels were quite low (except for the few TV
transmitters), so the receiver front end selectivity and string signal
handling was not an issue. However, in these days, there quite a lot

more signals and thus capable of producing many more intermodulation products popping up all over the dial and the signal strengths can be quite high (e.g. a nearby cellular phone), making some of the old designs useless in urban areas, while they might still be usable in rural areas. These designs might need an extra tuned stage in front of the mixer. Using very sharp tuned circuits, with higher losses, in front of the first RF amplifier will even further degrade the lousy noise figure of some tube RF amplifiers.

Geoff - thanks for nice site, with nostalgic associations, will browse there again.
The DjVu format offers major file compression - for explanation and examples see the BAMA site, eg
http://bama.sbc.edu/viewers.htm
...it works very well.

A nice PC board actually already exists that accomplishes much of this ($ 15 USD). You can surely tweak the design for your specific voltage requirement.

Here is the web page:

Not to mention there is a wax paper cap between the hot chassis and
the outer steel cabinet. It may not have been a serious problem back
then, but after 50 years most paper caps have developed serious
leakage and should be replaced, especially those that can place a
user in harm's way.

They are usually not rated to give their whole 300W output on the 12V
line though - most of it is 3.3V and 5V.

I guess it it too late for people to grab up old s-100 based systems, with their 8v 80 amp linear power supplies and use 4 of them in parallel. The ones I have left are still in operating condition so I don't want to gut them for the power supplies, never mind the fact that each one is about 60 pounds so 4 would be a mighty heavy power supply.
thanks, John.

May I jump into this discussion a little late?
1) There are three levels of license: Technician, General and Extra. Each one has a test requiring deeper & broader knowledge. Each also has increasing privileges.
2) Try to find a class in your area if that is possible! Being in a class setting is a way to get a lot of background.
3) If the class offers CW lessons, TAKE THEM!!!!! The only FCC CW requirement now is a single 5 Words-per-Minute test. TAKE IT NOW AND GET IT OVER WITH!!!
4) The best books out there are the Gordon West Q&A books sold at Radio Shack. They cover the entire test pool, question by question, and take the time to explain the answers.

It may not be easy at first, but keep in mind that kids as young as 5-6 years old have passed the Extra exam! As a 10-year ham & a Technician-Plus licensee, I assure you it can be done! Go for it & join the fun!!

Hi, Try this stuff. http://www.gwengibson.com/order.html It used to be sold under Circuit Bridge but their site redirects to Gwen Gibson. It's pre-sensitized silk screen. It keeps very well in the fridge. You can cut to just the size you need. I reconstruct the lettering using a digital photo and photo editing software, then I change the lettering to black. "Select" just the lettering and print it on inkjet transparency sheets once I get the size right. Use a sheet of glass or contact frame and expose per directions and rinse with warm water and you should have the screen you need. I use the thick enamels in the plastic squeeze bottles from Wal Mart's craft dept. Use a business card for the squeegee. Practice on something with a similar surface until you get the feel of it. If you make a mistake you can usually clean it up with water or alcohol if you don't let it set too long. I use a good masking tape to hold the screen in place on one end. You can also use the screen to make decals using the inkjet decal paper that have white or pastel colors. Something you can't do with the inkjet printer.

958. AD9835 and REFIN ?

AD9835 and REFIN ?

Hi

It's possible to control the output amplitude by varing the REFIN
input voltage ?

IOUT FULL-SCALE = 12.5 X VREFIN/RSET

VREFIN = 1.21 V nominal, RSET = 3.9 kW typical

REFIN Input Impedance 10M typ

From these equations the output is directly proportional to REFIN and
the recommended V REFIN is 1.21V. Is this means that the voltage
between 0 and 1.21 volt can be use to linearly control the output
amplitude, or if at least i can toggle the output via REFIN ?

Thanks for your collaboration.

Gilles

Doug: Dead VCRs often have nice sheets of aluminum as the top or
bottom of the cabinet. You can cut it with tin shears. Very useful.

I also use cheap cake or cooking pans available in supermarkets.

I'm told in the old days, enterprising young hams used to appropriate
STOP signs and turn them into chassis. But I don't recommend that.
Not aluminum anyway.

If you are into homebrewing ham radio or hifi amplifiers, I have three NEW power transformers that are just taking up space. If you can use one or all, they're yours for pickup in Kenmore, WA.

All have dual primaries with taps. Two transformers have a single 55V secondary with multiple taps, the third (smallest) has two secondaries, one 50V, one 28V, both with taps. The 28V winding is rated at 8A continuous. The largest transformer is rated at 250A peak, 6% duty cycle. Any of these would easily power a solid state kilowatt amp.

If interested, call Terry at 425-485-3188.

Depends on the sign. Most are, some aren't. I've spent enough
time at my employer's (a state highway department) sign shop to
learn that over the past 25 years. I've also seen the results of
a stolen STOP sign: the local sheriff's wife and two kids dead.
No, I'm not kidding.

But, aside from it being a felony in its own right and at least
manslaugter if someone dies as a result, it's not all that good
for chassis construction: it's too heavy and thick.

I use a local sheet metal shop. Not terribly expensive, and I
can actually talk with the guys and see specs on conductivity
and so on.

You didn't say where you live.

Here in southern California there is a place called Industrial Metals that sells all sorts of raw material at reasonable prices. Steel, aluminum, brass, copper, and so on. I built my entire dual band WARC two element beam from stuff I got there. Except for the clamps.

I'm sure there are such places in most metropolitan areas.

971. New program COAXTRAP

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-07 18:12:32 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aga0afgqv1@paris.btinternet.com>
Source record: 42832

New program COAXTRAP.exe

Coaxial traps are often inserted in HF dipole antennas to isolate the ends of the wires from the the feedpoint thus shortening the effective overall length of the antenna. The antenna is then resonant in a higher frequency band. A trap is a parallel tuned circuit which is adjusted to resonate at the higher frequency.

A trap is constructed from a length of coaxial line wound as a solenoid on a cylindrical former. The program models the construction operation by assisting the designer to wind on turns until the required resonant frequency is achieved. The normal coaxial capacitance behaves as the high-voltage tuning capacitance although there is a transformer action in the manner of connecting the ends of the line together. This small program will be interesting even if the user does not intend to make any traps.

This program has been tested by me on only two actual traps - one using 75-ohm coax and the other 50-ohm RG 58 on different diameter formers and different numbers of turns. Errors in predicting resonant frequency were less than 1 percent but great care was taken with measuring and checking dimensions. It would be appreciated if any constructors who have a trap in the shack doing nothing could measure it up and check frequency. If anything is suspicious please let me have the data and how it was obtained. It is possible on my solitary pair of samples I could have made a common error. The best way to measure resonant frequency is to use an antenna analyser on the Z range. Use a thin single-turn coupling loop around the middle and 6 or 10 inches of loosely-twisted pair to the meter. Look for a very sharp peak in Z.

Download COAXTRAP in a few seconds from website below. About 31 kilobytes. Not zipped up. Run immediately.

Source record: 42833
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I have just acquired over 700 pounds of bare #9 solid copper wire. I'm going to use some of it to redo my radial system, but the rest is for sale.

The lot includes lengths varying from about 33 feet to 37 feet. (Splice it together with pieces of 1/8" copper tubing to make longer lengths).

Asking $1.75 per length. (Less than 6 cents per foot!) 6 lengths for $10.

Pickup in Yorktown Heights or White Plains NY area. Will consider delivering nearby if you want the whole lot. Will also consider shipping if quantity is both worthwhile and manageable. (A 37 foot length weighs about 24 ounces. Buyer to pay shipping).

Watch for a rain trough/gutter replacement operation in your neighborhood. The guys that make the gutters on site have aluminum sheet in continuous rolls. I bought an 8 foot x 18 inch piece for $5 years ago.... I don't know what gauge it is but it works great for making boxes/chassis/panels. I've also used discarded aluminum siding from demolished buildings...

I've tried some decals with the ink-jet. Used the same Micro-Mark products. The major problem with ink-jet decals is the amount of transparency in the printing. So it depends a lot on the colors you want to use and the color of the background where the decals go. Often it comes out fine but on a dark colored panel it simply won't do.
Laser printing is considerably better. There's a few folks on the web who will take your artwork and prepare a decal sheet for a reasonable cost.
I've used one fella a couple of times with an ALPS printer that will print gold and white but am hesitant to recommend him because his 'day' job keeps him pretty busy and his turn-around time is quite unacceptable these days. He charged $13 for a full 8x11 sheet.
Something I've thought about but never investigated...the folks who run little shops for custom tee-shirts, coffee mugs, etc...wonder if they could do good printing of decals if you furnish the media?

I'm trying to raise some money to buy a SSB filter for my Kenwood TS-140S...

I have some laptop batteries, I have two Li-Ion 14.4V 2500mAh Dell batteries, $8 a piece plus shipping or 2 for $12 plus shipping. Never could figure out a charging circuit...

I also have a new IBM 9.6V 2.8Ah Ni-MH, $15 plus shipping (this is for an IBM TP365 and is $85 new). I have a 3.5" floppy drive for a IBM TP365 with the external cable/box for $10 plus shipping. I could make a deal on both ($20 plus shipping?)!

I have a Baycom type packet modem, N3PRT assembled from a kit but never wired up and tested, $12 shipped. I have a Ramsey 2 meter power amp with the sensing relay in a nice little alum. box. Worked but would never put out rated power, $15 - box connectors everything (no manual) plus shipping.

Analog devices AD9835 with a breadboard for experimenting (a little board with traces on it made by one of the genius qrp-l members), $10 shipped and includes two SMD Maxim chips (could've swore they were charge pumps...) mystery.

Original Neophyte receiver, assembled, with connectors pot vernier drive air variable, speaker w/headphone jack. Works FB. Mounted on a piece of plywood with a wood front panel, $25 plus shipping.

Speedex key, black wrinkle base, no shorting bar, $15 shipped.

Now to the oldies but goodies. I have a BC221 Frequency Meter, 125 - 20000 KC, Bendix Radio. In fair to good shape with calibration manual. I started a power supply and will include that also. Worked five years ago hasn't been touched since. This is not a museum piece but it did work and includes the calibration manual which is kinda rare (if you want to see one http://www.qsl.net/ab0cw/ral7.htm). Price is negotiable - plus shipping. It is heavy and I'd want to pack it really well. I don't need this one as I have a "brand new" one in storage.

I also have an Arc-5 shell with the roller inductor and variable capacitor. Best offer plus shipping. Sorry for the length of this post. And thanks.

Please reply off the list... Dan Reynolds KB9JLO

They have been used for receiving 1200 baud amateur packet radio on 2m by
putting the AF output into a standard packet radio modem. Outside their
upper frequency spec. but they work fairly well.

983. Summing loop PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-08 11:40:39 UTC
From: fred bartoli <toto@hotmail.toto>
Message-ID: <3d297a08$0$10518$626a54ce@news.free.fr>
Source record: 42845
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

Hello,

I want to design some HF (almost DC to 200MHz+) precision vector measurement (ABB & GPA/NA) equipments.

I know that HP (and maybe others) have some nice products, but for personal use, they are totally out of reach, even used, so I build. Another reason is that I very like the idea of competing with the big shots and see what I can do with rather limited means.

I will use a sligtly modified 100KHz lock-in detector for the vector measurements.

For the signal generation, I will probably use a DDS ref/pll loop upconverter, mixed down to the "baseband", allowing a simple single VCO design.

Here is now my problem :
It has to do with the sync demod reference frequency.
Wanting to get the most S/N ratio out of the beast, I don't want 2 high freq VCOs (one for the signal, and one for mixing with the output and return signals, down to the 100kHz IF reference and 100kHz IF signal), since I will have 2 x 2 vco phase noise to deal with (2 VCO, and 2 mixs - ref & signal).

So I've imagined another way :
Have a low phase noise (crystal generated) 100kHz sync reference, upconverted around the VCO signal frequency (hence having almost only one VCO phase noise), which mixed with the return signal, will convert down to the 100kHz target.

Simple direct mixing is not possible since eliminating one of the sidebands by filtering is impractical at 100kHz offset & 100s order MHz variable frequency.
Also for simplicity and S/N reasons I'd prefer avoid multiple IF frequencies / mixing stages...
And managing a precision IF, high dynamic range, amplification, sounds easier to me at a low 100kHz freq than at multi MHZ.

So I plan to upconvert the 100kHz sync reference with a PLL summing (mixing) loop :
My 100kHz demodulator reference will be used as the PLL summing loop ref frequency, driving the VCO (through the filter loop of course), the VCO output signal (FreqVCO) being downconverted by mixing with the signal output frequency (FreqMain, main signal VCO). The resulting product will be low passed, then compared with the ref.
Et voil&#65533;...

Reversing the loop filtering gain sign will even allow to select the mixed
product frequency (FreqMain + or - 100k)

But now I'm stuck with a "little" remaining problem : the loop nicely locks when the starting VCO frequency (FreqVCO) is inside a guardband around the target frequency (+/-100kHz), but outside this guardband the loop gain reverse then driving the loop into saturation at one end of the VCO.

Anyone have a clue of overcoming this little annoying pb ?

Oh, I forgot to mention that, of course, the summing loop phase comparator is a phase/frequency one.

Thanks for any answer/advice/comment, even about the general design philosophy.

regards,
Fred.

Oops - you are correct. That part of the circuit diagram was spotted
as having several errors at the last minute before publication. Most
were cleaned up on the circuit diagram on the website but the local
osc divider is still wrong. It also has wrong pin numbering on the
chip (it is a 16 pin device !). Apologies - will get it corrected.
The clock input connects to the top of the resistor and not to ground
as shown.

Dave

"OLD DAYS" !! ??

In the Olde Days, hams would boil 78 RPM records to peel the vinyl
off and use the aluminium 'substrate'.

As collectors' items, those records, now-a-days, in prime condx,
would probably pay for a full blown Icom/Kenwood/Yaseu station...

it is a useful idea to compare differemt cores if you wind 10 turns
and measure the inductance, and compare with other types. Just checked
an N77 core from Siemens today - I have no idea what it is compared to
the more familiar Philips 3C3 and 3F3 material

Estimate the reactance to be at least 4 times the impedance on the
lowest frequency

I don't know what the difference is, but when I looked inside my Kokusai MF-455-10CK, it wasn't that, but a MF-455-10AZ. The can had been opened prior to me getting my mitts on it. I wonder if these two are equivalents.

When I opened the filter two things surprised me. First, there are no disks, but bars. Second, the foam inside is perfect, not gooey at all. So I figure it must be okay.

Hi All

I want to use some ferrite cored transformers recovered from junked PC PSUs.

What are the best solvents to soften the glues used in assembly, but which won't attack the plastic bobbins.

Thanks

Mike

I disagree. You could not be more wrong. You could try, But you would not be successful. My point is that with dedication and study any one can build a 100% HB station for little money. Not, you - can - do - it - but - if - you - have - the - money - don't - bother. Although I only got my license a few years ago I got interested in the hobby about 25 years ago. I remember talking to a number of hams at the time and most of them built there first stations. The way they talked, building your own station was a right-of-passage into the hobby. When did hamming go from building to buying? I don't think that I am the rare exception, I think I am the interested ham.

Probably the actual mechanical filter is MF-455-10AZ. But when it's in the
can, along with the wiring, it's MF-455-10CK. Yea, I bet that's it.

I didn't find anything for those particular numbers in my 1993 HP Optoelectronics Designer's Catalog, nor on the current Agilent web site. I did find some numbers that are somewhat close, though, and they may give you enough info that you can figure out the details. It may help some if you find a date code on the parts...that could focus the data book search. I can likely locate newer and older data books than the one on my shelf. I suspect that the DC motors aren't actually included in the HEDS part numbers, but refer only to the encoders, but I may be wrong about that.

Cheers,
Tom

It seems like the design the ARRL published (assuming it's the same as the one I looked at) didn't take into account what the "stop" channel reflects back, which can be incorporated into the input reactance of the "pass" channel to good effect; also it's possible-fairly easy--to put a zero in each path to provide better stopping of the alternate frequency. I found that it wasn't too hard to design and build a rather better duplexer, but that said, I have to admit that I have access to some good network analyzers for "tweaking" (transmission response and return loss). (I suppose I should document my design and put it on a web page somewhere...)

Cheers,
Tom

Following a thread over in sci.electronics.misc (or s.e.somethingsimilar),
I see the most occurring suggestion to be to bring it up to temp in
an oven -- and then pull it apart using gloves.
Not much agreement on the temp -- 150-200D F seemed to be most
recommended. (Personal comment: Don't the insides of some of this gear
get up near 150D F.? Maybe 200-250D F might be the final 'selection'.)

The 'stuff' won't dissolve -- so 'they' say --
but it will loosen up with heat. One feller thought he was successful
with soaking it in MEK for several weeks. (Personal comment: By then
I would have forgotten what the hell I was going to do with it!)

1004. Building your own flexible VHF handheld antenna???

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-09 02:28:08 UTC
From: grant <5@6.7>
Message-ID: <YSrW8.29714$P%6.2315321@news2.west.cox.net>
Source record: 42765

Hello,
I am interested in finding out how to possibly build flexible handheld VHF antennas.

Any of you here done this before?

I have been given some suggestions as to using something like speedometer cable housing for the casing and also using guitar string for the antenna element wire. Cut the wire to the appropriate length and solder it to the BNC connector. Put it in the housing. Possibly epoxying the base or using glue filled heat shrink to stiffen the base and cap the top.

I am looking to replace an antenna for a VHF marine band radio. I bought this 15" flexible antenna http://members.cox.net/radiocheck/Antenna.jpg , about ten year ago from a marine electronics store called Neptune Electronic in San Pedro. It had no packaging at the time, and was just under the glass counter, and they said it was for the VHF marine band. It has been MUCH better than the stock 7" flex antenna that come with the Standard Horizon HX220S that I use, and as you can see from the picture it gets used a lot at work. In fact part of metal are falling out of the BNC connector on the antenna.

I could use a 30"(approximately) metal telescopic antenna which I have and get even better reception, but the length and stiffness of such an antenna breaks the BNC fitting at the top of the radio if the radio is moved around to much or to quickly as I do at work. So this 15" flexible antenna has been perfect because it is thin and light, but flexes if hit or the radio is jarred, and I move around a lot at work and need to have the radio with me. So I've also been thinking that the building materials could be something like using a bicycle break/shift cable housing, and using some good copper wire for the element. Any ideas as to what would be the best housing and element material, so that it would be as thin as possible, light and still flexible? And I really need this longer antenna because I need/like to hear stations that are well away from the harbor at times, further away than the stock 7" will receive.

These VHF FM marine band radios use a frequency range of 156.2500 - 157.4250 (plus 161.8000 - 162.0000 for "marine operator" repeater outputs). And this Standard Horizon has a transmit power of 1watt and 6watt.

I gotten a formula for cutting the wire to the appropriate length and here it is:

Now I don't know much about this stuff yet. And I am just assuming that I understand the 1/4, 1/2, 1/8 wave idea. Correct me if I'm wrong.

So using 156.800 (channel 16) as the frequency I get:

1/4 wave; 234 / 156.800 = 1.4923469, x 12 = 17.908162, x .8 = 14.326529 inches.

1/2 wave; 468 / 156.800 = 2.9846938, x 12 = 35.816325, x .8 = 28.65306 inches.

And looking at the math going on here I just assumed the a typical stock 7-8" antenna is 1/8 wave. Again, correct me if I'm wrong.

And going up in length gets proportionally better reception. Does that also mean the transmission gets better as well? Again, for my handheld, I want reception as the key feature I want out of it. After I hear someone calling for assistance I can run to the boat for best transmission on the fixed mount VHF marine radio if the handheld is not getting through to them.

Now there are antennas on the market that sold where they say that they "cut length to frequency". And some of those out there that look interesting to me are said to be "base loaded", and end up being not quite as long as a straight element antenna. One company called Smiley Antenna makes a model called the "5/8 Slim Duck" http://www.htantennas.com/2meter.htm that is base loaded. Would an antenna like this be better than a straight element antenna? Is making a "base loaded" antenna possible?

Well enough for now. Any Ideas?

Grant

1005. FS: BC221 Freq. Meter & ARC5 Shell

I have a BC221 Frequency Meter, 125 - 20000 KC, made by Bendix Radio. In fair to good shape with calibration manual. I started a power supply and will include that also. Worked five years ago hasn't been touched since. This is not a museum piece but it did work and includes the calibration manual which is kinda rare (if you want to see one http://www.qsl.net/ab0cw/ral7.htm). Price is negotiable - plus shipping. It is heavy and I'd want to pack it really well. I don't need this one as I have a "brand new" one in storage.

I also have an Arc-5 shell - case - with the roller inductor and variable capacitor and dials. Best offer plus shipping.

I built loops like that 25 years ago at Zeta Labs.
What we did in those days was to coarse tune
the VCO with a DAC and only allow the loop
to fine tune it. So in your case, the loop can
only tune the VCO 100 kHz, and you sum
in coarse tuning to get it within range. If your
VCO isn't already linear (ours wasn't) you have
to linearize it first.

We looked at various alternative schemes, but
always came back to this one.

What are the specifics of this station - what do you have in mind?
I called you an exception, because you said you built an excellent
receiver and a very nice 100W transmitter for $200. Are you saying
any one can build an excellent receiver and a very nice transmitter
for that price? Or are you talking about a receiver with poor
selectivity and poor sensitivity with a high noise floor and
bad IMD ? Is the transmitter SSB as well as CW, is it rock bound or
under VFO control? Note that I did not address the concept
of building just any HF station. I used your terms - an
excellent receiver and a very nice 100W transmitter.

You must have some compelling evidence to be so vehement
in your response - essentially, that I could not be more
wrong if I tried. Now here's what I said:
"You are an exception - a very rare exception.
MOST new hams will not be able
to put together a station that includes an excellent HF
receiver and a very nice 100W HF transmitter for 200 bucks,
even buying an old transceiver."
Ok. Show me where I am wrong. What percentage of new hams
do you think can build an excellent receiver and a very nice
100W transmitter for $200 ?

Not, you - can - do - it - but - if - you - have - the -
> money - don't - bother. Although I only got my license a few years ago I got interested
> in the hobby about 25 years ago. I remember talking to a number of hams at the time and

>
> Rick KC0GIX
>

If you talk to a bunch of hams today, you'll find a marked difference. Got my extra in '78, so I'm very familiar with what ham's were doing 25 years ago, when many did brew their stations. I was one of them

Source record: 42771

Hi all,
1200 Bd packet radio uses audible frequencies, it has nothing to do with capability to detect and pass frequencies below 300 Hz down to DC. Looking at the structure of TDA7000, I think it should demodulate these frequencies, but to obtain a clean smooth S-curve you should better connect your circuitry directly to the demodulator output - pin 4.

Message-ID: <3D2ABD52.2040209@att.net>
Source record: 42774

Doug,

1. Check your yellow pages for where aluminum is sold in your area.
Metal suppliers, machine shops, etc.

2. Check your local aluminum/metel recycling businesses in your area.
The variety of aluminum that gets recycled is sometimes amazing. There
was a 12 foot microwave dish there once (too big). I visit the recycling
business frequently and stock pile usefull pieces as they come in.

3. Recycling centers may be a source too.

Don N0UGY

P.S. Copper flashing for roofing can be made into very nice small boxes.

I am in the unpleasant position to announce the death of my 20 watt ANTEX soldering iron, although I tried what ever was possible to bring it back to life it was hopeless , nature took it course. I had it on for days with no complaints and was always there when I needed it. I was disappointed today when I turned it on and nothing happened and afterwards frustrated when I realized that I could not fix it . After 10 years together in good and bad (succeed home brewing and disastrous flops) it time to let it go and buy a new one. I wish that no home brewer has to part their tools (its like losing a part of you).

You should be able to resuscitate it by fitting a replacement element.
Spares for most Antex irons are available.

LOL! Did you at least give your soldering iron a decent burial, Deos? I've always made sure the loss of my tools meant something by donating their parts to other tools in need. In a way, it makes me feel like my tools live on in those other tools. :)

Hi. If I substitute the old regular VFO in my KW2000A, I can see that whenever the VFO output does up by 1khz, the readout must go down by 1 khz and vica versa.

Also, for each band there must be a starting position or starting offset. For eg, on 160, when the VFO outputs 2700 khz, the VFO must read 1800 Khz the actual output frequency. Then, when the actual rf output frequency goes up the VFO readout must of course go up, but the VFO output has to go down by the same amount.

And that must be repeated for every band, yet the starting offset will be different for each band. And the VFO must know when band has changed.

I suppose a modern VFO unit can take care of these things.

Thanks Rick for replying.

Could you tell more about the other schemes, because my VCOs will (I hope) be large range ones (150-250MHz tuning range for mixing down to 0-100MHz in one range), so getting them inside the capture range over all their tuning range, by open loop means, will be at least a real nigthmare.
Having more tracks to follow / build on, could lead me to the right solution.

Any comments about the rest of the structure ?

Regards,
Fred.

1029. FS: Lot of RF power Transistors

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-09 21:56:50 UTC
From: GaryH <garyh@bellsouth.net>
Message-ID: <VOIW8.1642$JU3.90281@e3500-atl1.usenetserver.com>
Source record: 42791

These are all new and have never been installed or used in any way.
I acquired these when I was working in the two way manufacturing
field many years ago and they have been in storage since then. I have
not tested these but I have checked all the junctions with an ohm meter
and they all look OK. I am not splitting these up but selling as one lot
and a simple check with RF power transistor sources will give you the
value of these items. I am cleaning out my collection of parts, so my
loss is your gain! Here is a list of the transistors and quantities. Some
I can not remember what they are but many are common devices used
in VHF power amplifiers.

DEVICE QUANTITY

2N5590 4
2N5591 2
2N6081 1
MRF221 1
MRF247 2
SRF2926K 1
CTC A3-12 1
CTC CD2772 1
CTC CD2773 1
RF2236 1
1421-2 1

The main value is on the first several items listed, a value of almost
$250.00 if you had to buy them new! Get them here at a fraction of the cost!

I have been asked to list some of my parts here but due to insane offers I
have
been forced to resort to Ebay. Make me a fair offer for these and we can
talk
or they will be Ebay bound.

Actually, I managed to get the originally posted address to work just after I posted saying it didn't work for me. Probably my fault!

The one trial I tried gave me results a few percent higher than those of a couple other programs I've recently evaluated fairly carefully and trust, though the results are certainly within a useable range.

One thing that I've found convenient for the way that I normally wind coils is to be able to enter the winding pitch, and let the program calculate coil length from the pitch and number of turns. That's nice because I normally wind coils either by using a second wire for spacing, or by winding the coil on machine screw threads. So it would be nice to be able to enter the pitch in terms of wire diameters (like 1.0, which is close-wound, or 2.0, which is two pieces of the same wire then remove one of them), or in mm (to match machine screw thread pitch). One of the programs I use lists out results for a range of number of turns, so you can easily see that your target value lies close to some number of turns which might be a little different from your initial guess. But that program works in US ("English") measurements, and I really do appreciate the availability of metric programs such as yours.

Cheers,
Tom
(My daughter is about to head off to study in Groeningen for a few months. :-)

Boeing Surplus? (Trouble is, it's typically in 4'x12' sheets there,
and the alloys available aren't always what you'd want.) In general,
I'd try sheet metal shops, especially places that do commercial
'lectronics work. You might be able to get small pieces for scrap
prices there, and in any event should be able to get larger pieces for
reasonable prices. I do NOT consider the prices I see in the
home/hardware stores to be reasonable!

Cheers,
Tom

No response for a few days now. I guess I should have asked first if building things yourself what what this "homebrew" group was all about. Any idea where I should post my question about this?

The RSGB VHF/UHF Manual has several. I built the solid state unit
designed by Larry Leighton that is built in modules.

I do believe there's a bigger difference between diplexer and duplexer
than just one letter. Is there a typo in the DIPLEX.TXT filename?

BTW, good going on the uuencode instead of base64 for the file. base64 stinks.

You could also try rec.radio.amateur.antenna where there is more focus
on antenna design and construction.

Also keep in mind that many people vacation around July 4 and may not
be online as much.

I would still be surprised if there were no off-the-shelf solutions
for you, although I do not do marine VHF myself. Have you tried a ham
specialty store?

Happy trails,

Thank you....

I did finally get feedback from Electronics Workbench, and they did acknowledge a problem. I had originally placed a few components on the top (by default that is where they all land) and moving them to the bottom, they got goofed. The footprint for the part I made worked out correctly as it was placed on the bottom to begin with.

I am slowly, but surely closing in on my new station clock, with Nixie tubes.

1042. Push-Pull Type Circuit Findings and Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-10 04:41:29 UTC
From: durabolin1@aol.com
Message-ID: <3d2bba8c.2800507@l158.ede.bit.nl>
Source record: 42604

I tried feeding a square wave into a push-pull circuit and it basically just short-circuited the primary. On the output my 'scope showed only little blips where there was a voltage change into the transformer. This surprised me in that I had heard that you could use square waves in a transformer, for example a square wave inverter works with 60Hz transformers. I then looked at the output from my square wave inverter and noticed the voltage wasn't square but sloped. I suppose this is the key in that the transformer needs changing voltages to work. Is there an easy way to get this slope or should I look at a less efficient design using a sinwave?

Also I was wondering if the secondary winding of the transformer in the above circuit will act like a choke to limit current like a normal inductor?

Message-ID: <3D2BF183.5030806@eznec.com>
Source record: 42606

The following assumes that the load on the transformer's secondary isn't what's causing the distortion.

To keep the distortion from happening, you need to have enough inductance in each winding that the impedance is high at the square wave's fundamental frequency. By "high", I mean at least several times the source impedance. If you had an infinite impedance, the square wave would be undistorted. As the impedance gets less and less, you'll see more and more tilt on the square wave. If you just see blips, you have much too little inductance. To think of this in the frequency domain, your transformer's windings only have enough inductance at the high frequency harmonics of the fundamental, so that's all that's surviving unattenuated. If you apply a sine wave of the same fundamental frequency to this transformer, you'll still see a sine wave, but it'll be greatly attenuated.

No, the transformer's secondary won't act like a choke, because of its coupling to the primary.

Roy Lewallen, W7EL

========
Agree with that , also in the UK aluminium sheet can be best obtained from a sheet metal workshop , involved in (among other) ventilation ducting. They usually have aluminium in various thicknesses ...and nice cutting and bending tools ,such that after you have marked and cut the sheet, they are usually happy to bend the material to a chassis and even are prepared to weld the joining edges.
Since for them it is an oddball job they will be interested in what you are going to do with it . From then on they will always be very helpful.

==========
To extend the life of any electric AC soldering iron , consider the
following :

Make or modify an existing iron holder with a hinge ,a spring and a
microswitch ,such
that when the iron is placed in its holder the micro switch is operated .
Wire a diode (with the proper rating) in the supply circuit such that when
the iron is resting in its holder, the diode is in series with the iron's
heater element.
The element is now supplied with half its normal power resulting in a lower
temperature.
When the iron is lifted off its holder the diode is bypassed , full power is
applied and (within
10-15 seconds,perhaps sooner) the soldering tip temperature is back to
normal.

Egads, that was well dredged up. Thanks.

That article is a good solution, yet my hearts desire is really to use a digital VFO, not simply just digital readout. I figure someone somewhere must be using a digital VFO with old valved equipment. However, that article may be okay in providing a digital readout for the 2000A. But I do wonder if a digital VFO with readout can be made to work. Perhaps I ought to contact a digital VFO manufacturer and see whether their product can be made to work with the KW2000A I have. But there could be a homebrew project that not only provides digital readout, but incorporates a digital VFO as well. That would be ideal.

Rich.

I've seen somewhere on the web a universal type synthesizer (digital
vfo) because I once had a similar idea. Of course once the synthesizer
is built, the digital readout becomes an easy add-on.
Anyway, the point I gathered from the article mentioned was that the VFO
tunes a single 200 khz range regardless of the band. It referred to a B
model...I suspect the A follows the same heterodying scheme.
Good luck,
Bill

An old trick which is well worth remembering. I think I first saw it
in SWM in about 1968 using a BY100 diode. Trust a Scot (should that be
two T'es) to publish it though ;-)

Bill

The A model is the same scheme. Unless I misunderstand the article, readout of the display simply goes from 0 to 200. When VFO outputs 2500 Khz readout is 200, when 2700 readout is 0. What I need is a display that will give the whole frequency, like 14250.1 Khz. And for each band. Don't know know yet how that would be accomplished, but I will in the end.

Rich

For a counter it would be done much the way it is done in the radio...by
taking a bit of signal from the carrier oscillator and from the LO for
the individual bands.

> -Bill

In the 2000A, you get the rf out, by basically adding (in "additive mixer")
455 Khz C.O. to the VFO (2500 -2700 Khz) then subtracting (in "substractive
mixer") output of each (Band change) HF Xtal Osc.

So, the math for 160m is:

VFO High:

C.O. + VFO = Output 1st mix.

(455 + 2700) = 3155 Khz

HF Osc. - 1st Mix = Rf out

4955 - 3155 = 1800 Khz

VFO Low:

C.O. + VFO = Output 1st mix.

(455 + 2500) = 2955 Khz

HF Osc. - 1st Mix = Rf out

4955 - 2955 = 2000 Khz

I think all you have to do then is to do the same in your VFO circuitry.
Three inputs for your display circuitry: Take the DDS VFO signal (2500 -
2700)) add it to the 455 Khz C.O. then subtractively mix with the output
from the HF Osc and feed that to the display. But, I don't hardly know what
I'm doing. :c).

Biut I would have though that maybe you could program these things into a
programmable VFO, with no need to take inputs from your TX/Rx oscillators.
I thought that might be one of the beauties of a modern synthesized VFO.

> I thought that might be one of the beauties of a modern synthesized VFO.

In other words the only connection between DDS VFO is output of VFO. On
""band 1" I programme the display to take VFO output, add C.0. (appx 455)
then to minus that summation from 4995. Etc, for each band with different
HF osc frequency.

Problem is though that when you change sidebands the C.O. changes slightly
in this rig. And things change again when using CW, so that calls for a
sophisticated display programability function. So, taking signals from C.O.
and HF OSC might well be the best solution anyway.

The one I'm thinking about and I can't remember who did, exactly what and where it is, do *exactly* what you want. It is controled by a PIC (IIRC) controler with digital readout (controled by the ÂC). The software had ALL the bells and whistles you could dream about, with by band programmable offsets and offset signs for easy USB-LSB, ... (sorry don't remember exactly all the details since I'm not ham, but I'm pretty sure it meets 100% your requirements).

Go on searching. I'm sure it is a DDS based VFO.... and TILT!!! I now remeber very well...

Ok, I verified. It's the one I thought about.

Go on www.analog.com and download an app note AN557 by Ulrich Rhodes, and give many thanks to this guy.

Fred.

I've always preferred a SMPS pre-regulator followed
by a linear regulator to gain the best of both; you'd
pre-regulate to about 2V above the desired output
and use a linear regulator to arrive at the
target voltage.

Some years ago RF Design offered some programs on a 3.5" floppy. One of these was COIL.EXE. Of all the solenoid coil programs I have had- this was the easiest, most useful and dead accurate. Unfortunately the machine it was installed on died.
Anyone have a copy of this program and could send it- must have been quite small- perhaps 50K or less.

Thanks,
Dale W4OP

Quite a few rigs will shift on the digital readout when selecting
between USB/LSB/CW because you really ARE changing freq. Of course it
will always be more accurate to sample the actual oscs rather than
re-create oscs specifically for a readout

> I called you an exception, because you said you built an excellent
> receiver and a very nice 100W transmitter for $200. Are you saying
> any one can build an excellent receiver and a very nice transmitter
> for that price?

Yes.

> Or are you talking about a receiver with poor
> selectivity and poor sensitivity with a high noise floor and
> bad IMD ?

Receiver
sensitivity
1.0000MHz .72uV
5.0000MHz .56uV
10.000MHz .36uV
20.000MHz .38uV
Falls off from there but thats ok, I generaly stay in the 80/40/20 meter bands

selectivity
+/- 3 kHz from center Frequecy (Fo) 12 dB
+/- 5 kHz " 35 dB
+/- 10 kHz " 60 dB
+/- 20 kHz " 70 dB

Noise is less than 10dB through most of the range but does run a bit higher on 80m

Is the transmitter SSB as well as CW, is it rock bound or
under VFO control?

CW/AM. I don't particulary care about SSB. I started out rock bound then moved to VFO when I
added AM. But the embedded designer in me would not leave it be so I made it digital so I could see the frequency on an LCD, although the VFO was FB.

> Note that I did not address the concept

I know that there is a difference in hams today and most do not want to build. I find that sad. I get the feeling that a lot of people stay away from the hobby because of lack of

funds
since they erroniously believe that you need a big bank roll to get into it. All the time ignoring the best part of the hobby, HB, scrounging, and putting forth as much effort to learn the dark art of radio as they have time for.

Good point. When I was first licensed back in 1954, I built all my own gear because I couldn't afford to do anything else. I also discovered I loved designing and building things. These days I lack the time and space to do much scratch building, but I love working with old tube gear. Restoration and use of antique radio gear can also be quite satisfying, and you don't have to spend a bundle if you don't want to. I have an all vintage HF station that is a lot of fun to operate. Takes me back to the days when things weren't so sophisticated.

I have a counter/PLL stabilizer that will do this
The main counter will count the VFO freq to 10 Hz resolution. There is a 4 bit interface to select various offsets to 10 Hz resolution - this will give 16 possible offsets, positive or negative. eg one bit could be used for USB/LSB and the the others as band select (ie 8 bands)
You can also stabilize your VFO with a "huff and puff" PLL scheme if you place a small varactor across the tank (enough to give about 5 KHz swing).
The board uses an AVR controller

see http://www.iinet.net.au/~richardh/VK6BRO.htm

There will be an article in Circuit Cellar soon.

I've got to replace the radio in my car, and I'm interested in replacing it with a homebrew SW receiver (built in an old car radio chassis), prefereably something with reasonable coverage up to ~30MHz. Has anyone done this before? I've found lots of good plans for SW radios, but none that appear to be suited for use in a car.

You can use the cassette player as an input device to a regular car radio (RatShack has adapters), then just put together one of the QRP regen receivers from the ARRL Handbook.

MFJ and probably others (Ten Tec?) offer SW converters for car radios.
That way you get to retain the good audio system present in a car radio
and add just those bands you wish on the converter.

I have a Gonset Tri-Band converter that was designed to go ahead of a car radio to provide ham band (and some SW BC) reception. I'd like $25 for it. It's tubes, so needs a high voltage source maybe 150 V but I built a little transistor converter to run it. Great little unit.

Hi Dale,

That's the one I've used, too. Recently I've needed some coils I could wind quite accurately, and I discovered an error in that program! The coil length, calculated from number of turns and pitch, was in error by one turn. So I went looking to see if http://64.130.134.245/saratogasoftware/ had a corrected version. Well, there was a new version, windows-ized and with a lot more machine screws for standard formers, but the error persisted. I emailed John (John Mezak, K2RDX, who wrote the prog.) about it, and he promptly corrected the mistake. The program now gives results even closer to what I measure with careful measurements on HP/Agilent equipment and in other ways for a few samples I tried. I highly recommend it. However, I feel obligated to point out that the program is now shareware.

If you want to avoid shareware, I find that PCAIRL gives very accurate results, too, though I don't like the way that results are presented quite as well. You may actually like the user interface better; it depends on how you like to go about winding coils. You can find it free at http://www.alkeng.com/.

Of course, Reg Edwards also has a coil program on his site. I didn't find its results to agree with my measurements quite as well as the two above, and still like K2RDX's program the best for accuracy and convenience with respect to the way I actually construct coils. There was also yet another one mentioned here just a couple days ago. Both it and Reg's are in metric measure, and the other two I mentioned above are "English" (American).

Cheers,
Tom

Richard

Many thanks.

At the moment I'm torn between a digital display + synthesized VFO and a digital display + PLL scheme to keep the rigs own VFO on frequency (or even a new outboard VFO on frequency). I think that it's probably a simpler and cheaper project to just make a display + PLL.

Anyway there are probably a lot more, but to recap these are three solutions, the last I think too basic.

Synthesized VFO + readout
http://www.analog.com/library/applicationNotes/dataConverters/dds/AN557.pdf

PLL + readout
http://members.iinet.net.au/~richardh/vfostab.htm#Introduction

PLL + readout

Looking for a couple of items......
tuning cap rated 10-1200pf @4kv
Load cap 50-1000pf 2kv
these are for a 3000k @ 3 amp transformer
i am going to use a GU-84B tube.
Trying to get together the parts i need for this amp.
any built one using this tube for hf 10-160 meters?
I have all sorts of stuff to trade on also have many caps smaller for
smaller amp projects some roller inductors etc.
the values listed above are on a schematic i found on this tube....if
someone has a better idea i am open to all sugestions.
Also will have to pick up a tube and socket ....really everything for
the RF deck. I have the plate transformer under control its a pole pig.
i could use a heater grid transformer.
thanks for looking

Here is my .02 worth, try a good eclectic junkyard (i.e the junkyard wars type) that collects more than just old cars and trucks. I have a place near me called Petry's in Westminster MD that often gets some real nice aluminum scrap from an aircraft manufacturer, and will sell it to me for 50c per pound. I have gotten everything from 5/8 inch seamless aluminum tubing for antenna elements, to 1/4 inch aluminum plate for boom to mast clamps. It can be hit and miss, but the price is right if they got what you need.

This is a Plessey part, I think, just based on the part number. I think that they were bought out and the SL1612 and other standard rf ic's were probably taken completely out of the product line of Plessey per se. Going to the website now, all they seem to have are microwave parts for 2.4 and 5.8 GHz. I could probably help you with the MC1350P, but I would need the data sheet for the 1612 so I can see its internal schematic, so you're in a Catch22 here. As a guess where to go now, try Phillips or Siemens and see if they may have bought out the rf ic's from Plessey. In the mean time, I'll look through my old stuff and try to find a schematic of something using this part.

Finger stock in an office supply store? I doubt that. This is esoteric stuff. You need to go where you can get EMC materials. That may be a problem as these people tend to require bulk purchases. If you know an engineer or if you're an engineering student, I would look in the Gold Book or other source for the EMC vendors and get some samples. I used to have a sample kit, but got rid of it long ago.

You may want to try vendors like McMaster-Carr. They will sell various
interesting materials in small quantities. It will cost a little more
per unit, but you don't need to buy a 50 year supply.

I suggested taking the CW right off because I have a sneaking suspicion the mossbacks at the ARRL are going to fight to keep some sort of CW requirement in place no matter what happens at the WRC 2003 meetings. Also, although I don't operate CW, I had a VERY good CW teacher at the classes I attended. Out of 27 people who took the course, 27 passed both the written & CW tests for Tech +.

1108. Help! Need help restoring Philco Transitone

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-13 18:41:41 UTC
From: msenecal1@juno.com
Message-ID: <62bf14a6.0207131041.5d513233@posting.google.com>
Source record: 42720
Cross-posted to: rec.antiques.radio+phono,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I just recently came into a nice old Philco Transitone. I don't have pictures of it yet, but it's small, a dark brown bakelite, with a speaker on the left, and a squareish white and gold tuning display on the right. There are two knobs right under the display. The whole thing looks to be from the late 30's, and looks like something that would be on a detective's desk in a noir film.

The problem is that the speaker was completely shot. In order to take it out, I had to remove the speaker transfomer, which was riveted to the speaker. I accidentally clipped one of the leads too short, and I don't think I can re-use the transformer(but may try). I have a speaker that will fit, but I can't find a match for the transformer. It takes 4 leads, and is labeled 5575. I have no idea how to match it. Anyone have any suggestions or ideas?

Thanks,

Matt

1109. Re: Can digital VFO's do this..

A digital vfo would work in place of the older rig' normal vfo. But, it wouldn't show what the actual operating frequency was. Remember a rig's vfo operates in a certain 500 kHz band. If I remember right the Yaesu FT-101's vfo was 7.0-7.4 Mhz.
So your digital vfo would only need to work in the same frequency output as the original vfo. PLus yuou woiuld need to match impeadance and signal level.

The circuit in the article was a real good way to do digital display on older rigs. Because you actually counted the frequencies, either up or down, of all of the oscillators in the rig.

Even the later FT-101ZD and Kenwood TS-820S with digital displays simply counted the vfo frequency for the Khz and used the band switch to determine the Mhz. While theft would display vfo drift. They could not track drift in the other oscillators.

Hi,

If I understand correctly, a GPS receiver has a 1pps output that is precise.

What's the best way to use this as a standard to adjust/compare to a 10MHz standard?

Any advice is appreciated.

1114. Help with Hamtronics TA-51

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-13 22:59:56 UTC
From: Paul@Rasdoc.com
Message-ID: <a8190e1f.0207131459.57e63bc@posting.google.com>
Source record: 42727

I just finished a HamTronics TA-51, and I can't seem to get it to
tune up.
If you have never seen a TA-51 the rest of this post won't make any
sense....

No matter what I do I can't get it to draw more than about 220ma and
produce about 0.8W.

I am running it at 13.6V (Measured at the board, < 75mv ripple)

All of the signals look normal However the output will just not load
up.

I am using an RF dummy load and it measures 50 ohms at the end of L14,
so the connections are good.

Looking at the collector of Q7 with a 150Mhz scope I see:
about 28V Pk to Pk or about 10V RMS

On the base of Q8 I see a about 3.5V pk tp pk

On the C50,C51 junction point I see:14V pk to Pk, but making
the measurement with the scope changes the operation of the unit.

The voltages around Q7 and Q8

Q7 e=0V
Q7 b=+0.14
Q7 c= 12.96

Q8 e=0V
Q8 b=0V
Q8 c= 12.93

Any Suggestions?

Paul Kl7JG

I haven't built mine yet but I intend to do it this way;
Use the 1 pps to sample the 1 MHz from my standard (narrow pulse)
Feed that sample into a sample and hold circuit (charge a capacitor)

Connect that to an OP amp
Use the OP amp output to adjust the 10 MHz standard (in my case 5
MHz)

My GPS receiver can put out 100 pps as an option so I will use that
instead of the 1 pps.

I built a LORAN receiver using the above scheme and it works very well.
The
LORAN pulse rate is about 12 pps so the above should also work

Anyway that's what I am doing.

There are for more convenient and accurate means of obtaining frequency and time standards than GPS.

There are world-wide standard frequ and time standards. All the way from VLF to 25 MHz. There is one at 10 MHz.

Most broadcast stations can be very accurate frequency standards.

Any communications radio receiver can be the comparator.

As a radio amateur you should be familiar with the procedure.

OR if you don't want to build a unit you can use a dedicated GPS timing/frequency standard by picking up a surplus HP Z3801A unit. See:

www.realhamradio.com

under projects for info. I've got two of them at the workbench and use the 10MHz reference standards to drive the test equipment for super accurate measurements. These units also provide the 1PPS output in addition to the 10MHz ref...the unit uses the GPS info to "discipline" a highly accurate oscillator that resides in a double oven.

If you have the exact model number, you can get a schematic diagram at
http://www.nostalgiaair.com (Click Riders, then find Philco, etc...)

It probably uses a 50L6 or similar for audio output. This will want a
2500 Ohm to 4 Ohm transformer (assuming 4 Ohm speaker...). If you can
find a speaker with attached transformer, it will more than likely be
OK. A 5K to 8 Ohm one would work perfectly as well. If the speaker
truly is shot, drill out the rivets and reuse the transformer - splice
to the leads if you need to.

You want a connection to the wire mesh in the concrete, it is a Uffer (may be spelled wrong) ground. The best way is to have a continuos bare wire loop around the basement in the concrete and bring out one point to ground everything. Ground rods will not come close, as the wire in the concrete will have a larger surface area.

Ok,

So now I have to say what I am really trying to accomplish...

I picked up an HP-105 Quartz oscillator recently. The fine adjust had been monkeyed with. Understand, this unit, when I set the fine adjust to nominal is to the best of my ability to measure, better than anything in house.

I figure sometime I might borrow a GPS receiver and see how it is really doing. It is better than 1 part in 300 M to be sure.

It isn't a two-transistor project, but there was an article in QEX or QST a few years ago, describing a unit for which boards are available. The name that springs to mind is Brooks Shira - try seaching the web, because a number of people have built the project and there's bound to be discussion about it.

====
A 5000 to 8 Ohms transformer has a winding ratio of sqrt 5000 /sqrt 8 = 25
to 1.
If the impedence ratio is 5000 to 4 the winding ratio is approx. 35 to 1.
If you can't find an audio transformer with a winding ratio in that order
of magnitude which can handle the anode current of the tube, you could
resort to another transformer ,say 110 V in , 3 - 5 V out, or 230 V in , 6-9
V out.
Acceptable sound quality ? ...I don't know ,but it is worth trying .

Note : Finding winding ratio of any unknown traansformer ; apply approx
1V -AC to secondary winding (which should have the lower resistance of the
two windings) ,measure voltage across both windings (preferably with a
digital AC voltmeter) and determine their ratio.
For this test you can use any low voltage AC source ,preferably a
transformer with a variac.
If you have an audio signal generator and an audio voltmeter (most digital
handheld AC voltmeters nowadays are OK for up to a few kHz) you can get
adequate info on your transformer's frequency response by varying the audio
frequency while measuring the output of the other winding.

While there are indeed many frequency standards being transmitted, it is my understanding that due to multipath and such the accuracy of a calibration is limited to something like 1e-7 or if things go very well, 1e-8

Using 60 KHz from WWVB reduces multipath and so it tends to provide better accuracy than a signal ad 10 MHz. This is why calibration labs always used 60 KHz as the signal to calibrate to.

For that matter, it is simpler to construct a 60 KHz calibrations system than a GPS synchronized system.

But a good GPS lockup can get 1e-9 or better and so that is a more precise standard.

The circuitry involved is complex and more trouble than a typical amateur operator needs. For most hams, zero beating with a signal off the air is enough. Still, for precision, GPS is hard to beat.

I was looking for data on the SL560 and found this:

http://products.zarlink.com/obsolete_products/

The SL612 is there. It's similar to the SL1612.

A lot of GPS units have some short term jitter in the 1pps signal.
the signal is specified as +/-1usec for a generic unit or 100nsec for
a timing unit.

For a single 1 sec interval 1usec is 1ppm while 100nsec is .1ppm
So the solution is to measure over a much longer period and
displine the osscilator.

The basic process:

Keep a counter counting the osscilator output.
At every pps sample this counter and see if the count is ahead or
behind where it should be.

Then use this error term to adjust a DAC controlling the osscilator
adjustment voltage.

The time period to sample over can be variable.
When you are just starting up the osscilator one can probably make
adjustmets every pps or every 10pps.
After everything is warmed up syncronized and stable then
one would set the adjustment time constant to a much longer interval.

I've seen syncronized Rb sources with this time constant measured in
days.

Dino is correct, the HP Z3801A unit is a great buy (A 6 channel Motorola Oncore GPS is inside !)

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=1365847440

This dealer sells them now for $ 289.00 and had over 1,000 in stock (refurbished surplus from cellular site upgrades)

The K8CU site will fix you right up, how to jumper for RS-232 from RD-422 and a couple of sources for the 48 VDC power supply (e.g. Jameco)

I would like to see some numbers on the accuracy of the signals mentioned.

I intend to only use Loran (while it is available) or WWVB or GPS. all others
have questionable accuracy, according to my info.

An AC transformer like this won't work (well) unless you place an air gap (fish paper) between the core "E" and "I" sections. The DC plate current will otherwise saturate the core. This in turn could "roast" your output tube.

======================

Actually, this IS the main question to consider first... As I mentioned, most hams would find calibrating to WWV more than enough.

Using WWVB or GPS involves somewhat more complex circuitry and may, or may not, be worth the trouble.

On the other hand, considering the name of this newsgroup, it may be fun to build a super accurate frequency standard even if it IS overkill :)

======================

In my case, I am dealing with 10 GHz (and higher) frequencies where a fraction of a PPM error multiplies to a large shift in absolute terms and that plays havoc with synchronizing both ends of a link.

I plan to construct the GPS system by Brooks Shera mentioned in QST a few years ago, check out his website for details:

http://www.rt66.com/~shera/index_fs.htm

Here is his original article from QST:

http://www.rt66.com/~shera/QST_GPS.pdf

=============

Oh yeah, I noticed the TAPR website claimed to be designing a plug in option for their TAPR project to give GPS derived accuracy but that preliminary announcement hasn't changed for quite a long time now. Anyone know if they are still going to offer this ?

Good point on the jitter problem and the need for averaging. Also remember
that your
oscillator has some short term instability so in your averaging you can
reach the point
that you are not sure if the GPS signal is noisy or your oscillator is
noisy. At that point
(or before) you have to reduce the averaging interval.

I am not really a designer but build things anyway.

Everything is "make offer":

* Motorola MOCAT model 4020 CB radio. This is the one with digital display and Extender button (proprietary noise-blanker). This radio is close to mint, works perfectly, with the original box. The mic is a bit sun-tanned.

* Hickok model 121 (cardmatic) mutual transconductance tube tester, includes cards for 322 tubes for many of the most common types. No manual included but one is on the net somewhere. Works fine. Weight approx 50 lbs.

* JVC model 3050, AM/FM/PB, 3" B/W TV, w/AC adapter, only defect is the antenna tip broken off.

* Tubes, all pulls, all tested strong.

6BG6GA, 6BQ6GA/6CU6, (2)6LF6, (3)6146 GE, 6146A Raytheon, 6146B RCA, (2)6AC7, 6H6, 6SN7-GTB, 12SL7-GT, 6V6GT matched pair

I also have hoards of miniatures. Let me know what you are looking for.

* Transformers, all are 120 VAC primary:

52C026 G (from Hallicrafters S-40)
640 VCT @ 100 mA (350 VDC with a 5Y3)
6.3 VAC @ 3 A, 5 VAC @ 2 A

F54-124 549-6426 (from Heathkit GW-22)
100 VAC @ 80 mA, 6.3 VAC @ 3 A

18-412 606136 (from I can't remember what)
545 VCT @ 100 mA, 6.3 VAC @ 2.5 A

I don't know about the original poster's needs, but the standard ham
reason for needing this accuracy is using the 10 MHz to stabilize
the frequency at 10 GHz or higher. This worsens the accuracy by a
factor of 10^3 or more. Typically we are using SSB which is fairly
narrow BW. At these frequencies there is enough uncertainty on
antenna pointing for longer contacts. If you can remove frequency
uncertainty to 10's of hertz or better contacts are much easier.

There are new digital modes which are even narrower in their BW. To
use these at 10 GHz or higher for long distance weak signal work
requires major stability and accuracy at the 10 MHz reference.

I know Bill, K7NOM is one of us, because I have talked with him on
10 GHz.

1150. SM0VPO Homepages Update

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-15 08:43:22 UTC
From: Harry SM0VPO <someone@microsoft.com>
Message-ID: <agu2umhig1@newstoo.ericsson.se>
Source record: 42663

Hi to everyone at RRAH,

It's been quite a few months since I last posted anything here, in fact it is about a year ago. Harry's Homebrew Homepages is now located at http://w1.859.telia.com/~u85920178/ where there are no banners to slow down the traffic. There are no outages due to excessive traffic since there is no bandwidth limit. It is just a bloody dificult URL to remember!

During the past year, I have been hounded by demands for payment to "freeservers.com" (or should that be "FEEservers"?) so I have moved the page http://sm0vpo.8m.com to http://w1.859.telia.com/~u85920178. Some of you may be aware that PMP3.NET was hacked and eventually closed down due to the misuse. This took away my free homepages that were kindly hosted by PMP3.NET.

There is a new messageboard too, also without banners. A new FAQ (Frequently Asked Questions) and FASQ (Frequently Asked Silly Questions). All the old ones have been kept, but some new ones have been added, Eg: "How many volts do I need to kill someone?". During the past 12 months, Harry's Homebrew homepages (http://w1.859.telia.com/~u85920178/) has had quite a few additions. Some of the latest project examples include:

EPROM AF Generator (still under construction).
WAV to EPROM conversion.
Many synthesiser projects.
DC-DC voltage converters (including 90v DC for battery portable radios
- still under construction
- JPG "skins" to be posted shortly when i get a round twitt.)
150mW FM TX (88MHz - 108MHz) (technique Ok for 145MHz).
Synthesised FM TX (88MHz - 108MHz) (technique Ok for 145MHz).
Antenna Z bridge for Spectrum Analyser.
Antenna Questions & Answers (Eg: "Size isn't everything!").

H.H.H. now has just three sites, but no mirror sites. they are all located at:

PROJECTS - http://w1.859.telia.com/~u85920178
Unlimited bandwidth, Full site, No advertising, SWE

VISITORS CIRCUITS - http://hem.spray.se/lythall
Selected visitors submitted circuits - SWE

PDF LIBRARY - http://hem.passagen.se/sm0vpo
Unlimited bandwidth, Full site, SWE

So perhaps I may have the pleasure of a visit from you. Whatever you do, have fun with antennas, homebrew, radio and electronics in general. Very

best regards from Harry Lythall - SM0VPO

> 73 de Harke, PA0HRK

The only two devices that have both a 488 and 232 port on them that I can think of were the Commodore Superpet, and the Osborne line of computers. Commodore used 488 as the interface to their disk drives and printers and the Superpet was the only model that also had a serial port built in. Osborne used the parallel port as either 488 or centronics interfaces.

Both of those solutions would involve using a 20+ year old computer as a protocol converter, can't you still find pc boards that offer 488 ports? I recall they used to be available in the back of magazines like Popular Electronics.
thanks, John.

There are RS232 to 488 converter boxes available from at least two companies
as I recall. Try National Instruments for starters.

Lately, I've been running lots of GPIB automated tests to look for spurs and characterize the behavior of various loop filters at different frequencies in an octave-band microwave synthesizer design. This particular tinkering frenzy has been going on for several months. Because I keep my spectrum analyzer locked to GPS and my clock source calibrated against it, it's easy to do A/B comparisons on hundreds of screenshots taken months apart. In some cases, these readings are taken at 100 Hz/division or less, so it actually is nice to have < 1*10E-8 stability to keep the graphs from drifting off-center.

It's hardly mandatory -- I could get the same benefits by locking the analyzer to my signal generator's internal standard. In any event, a good OCXO from any number of manufacturers would be stable enough for what I'm doing at the moment. But it really doesn't cost that much more to set up your own GPS house standard and settle the whole what-frequency-am-I-on? question once and for all.

The Philco TH-4 appears in Riders vol 11 Philco page 4 and 6.
The Philco TH-16 appears in Riders vol 12 Philco page 1.
You should be able to find both at http://www.nostalgiaair.org. Click on
the Riders Online link, scroll down to Philco, then down to your model
number.

Hello, all...

I'm interested in home brewing an AM RX antenna for my stereo. It has a two-conductor input for an "AM Loop Antenna". If I build something do I have to worry about impeadance matching (i.e. balun, etc.)? Anyone know of some good design ideas? I'd like to be able to try some DX RX-- perhaps with a directional antenna.

Interested in hearing any ideas you might have..

Different commercial stereos have different loop connections. Some of them are truly balanced inputs, but many of them are grounded on one side with the other side connected to the single-lead antenna input. Almost all of them are NOT tuned inputs, and the tuning is either digital or with an internal loopstick.

That being said, try building a large antenna loop of about 250 to 300 uH and run the leads into the house via 300 ohm twinlead (nothing important about the impedance, but the line has low capacitance). Hook up a 365 to 400 pF varicap across the twinlead to make a tank, and then down to the loop input. You can tune it inside, but you need to go outside to rotate the loop. That works pretty well.

You could also try the longwire approach: Use the same varicap with a loopstick (again, 250 to 300 uH), but wire them in series. Put one end in the air to your longwire antenna and the other end to a GOOD ground . Then wind a few turns of wire around the loopstick and into your loop inputs. How well this works depends on your antenna and your ground. I have used lots of things for antennas, such as a chain-link fence (ok), a barbed-wire fence (better), and even a large steel garage (not too bad at all). The ground should be water pipes at the very least; water pipes with a couple ground rods would be better.

And ALWAYS remember to use some form of lightning protection!!!

Use the 1pps signal to gate a counter on and off while it counts
pulses from your oscillator. In one second it should count to
10,000,000 +/- 1 count. If you can divide the 1pps signal by 10 or 100
then you should be able to improve your accuracy by the same factor,
but you will have to start worrying about jitter in the divide by
circuit.

You didn't mention what brand of stereo and that may make a difference
as sometimes there was an external loop specific to the set. I had an
AIWA that used an external loop and thats how the rear panel was
marked...a little square thing with about 10 turns of wire on it that
you could mount wherever it was convenient and orient for best
reception. I don't recall that there was any internal loopstick
antenna. Its still around here somewhere if additional details would be
helpful.

The loop connections on modern receivers are connected to a few turns
on the loopstick (or the single-ended input of a ditigal tuner). I
haven't seen tuned external loops used on any commercial AM radio
since the old tube-type superhets. You can hook up just about any kind
of loop imaginable to one of these modern stereos and it will work to
some extent, and if it's tuned it will work a lot better than the
wideband loop that comes with the receiver.

I've been looking at a couple of these miniature FM transmitter schematics on the web and I have been wondering if I could calculate the exact output power of them, then hopefully alter one for my needs. Would this be possible knowing little about the antenna? The antenna will probably end up being a quarter wavelength wire if that's any help. I mean, if there was some resistive load there, the output power would be obvious, but what about when there's just a wire that says 'Antenna'? Thanks.

Al

The 'Suffolk' is a very good design, but it's only published in the
book, not on the web.

Web site - which has changed, see below - only contains the revised PCB
layouts and various minor updates to the book.

news:<m0mV8.126$Y72.339912@rdr1.wex.teleglobe.net>...

Recal the first battery pack vented when fast charged using a
negative delta voltage charge termination. A friend suggested
trickle charging and discharging several times (conditioning)
before fast charging. This worked on the first battery pack.
I then received a second pack. This time I trickle charged
and discharge before trying a fast charge. These are the
results.

I trickled charged 4 times at 0.05ma for 24 hours. Each time
I discharged to 6 volts (1 volt/cell) at 200ma, recording the
capacity delivered by the battery. Capacity numbers were
897ma-hr
939ma-hr
945ma-hr
943ma-hr
So the battery capacity improved with cycles and leveled about
945ma-hr.
I then increased the time by 2 hours to make sure I was reaching
the maximum capacity. Capacity numbers were
946ma-hr
948ma-hr
It appears that is the best the batteries will do.
I now fast charged with negative delta voltage termination at
550ma (1.72C), twice. Both charges went perfect. Maximum
battery temperature was 47C each time. Panasonic says this size
battery (A) should not be allowed to exceed 55C. Capacity numbers
were
905ma-hr
904ma-hr
This points out something Linear Technologies sayed in their
application note on charging Ni-MH. That is that when a charge
is termiated with negative delta voltage the battery is only
at 90 to 95%. Unlike Ni-Cd which will termiate at 100%. Linear
recommends toping off the charge with a trickle charge.
So I did a third 1.72C charged followed by 2 hours at 0.05ma
to top it off. Capacity number was
959ma-hr
I also fast recharged a fully charged battery to verify a voltage
peak would be detected and the battery would not be over stressed.
It detected a peak in 20 minutes. Although I did not record the
temperature, it felt no warmer than before. I plan to do this
again and quantify the temperature.

1170. Re: RF Output Power from Schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-16 16:49:57 UTC
From: Bob <balbert@cnmnetwork.com>
Message-ID: <V8YY8.176064$lm2.8618193@bin2.nnrp.aus1.giganews.com>
Source record: 42683

To calculate the output power you need to know the load impedance. If the impedance is mostly reactive, there won't be much antenna current. To maximize antenna current you will need to resonate the reactance.

Even if you do that, you still are faced with the probable mismatch of the remaining resistive component, as compared to the design of the amplifier.

The best way to get maximum out is to use an antenna of the correct impedance. The second best way is to use an impedance matcher to convert the actual antenna impedance into the best one for the amplifier. In both cases you will be able to figure out the power, but unless you know the impedance there is no way to make any calculations.

Two corrections.

The trickle charge was 0.05a or 50ma. Not 0.05ma.
The fast charge was done at a rate of C/1.72. Not 1.72C.

I am British writer working on a feature about men and their sheds for M Magazine. Perhaps your shed is a second home, you use it for inventions or perhaps you have a comfy armchair, TV and a couple of beers. If you live in the UK and are interested in having your shed profiled in the magazine or would like more information please e-mail me on lizscarff@hotmail.com
Kind Regards
Liz

1173. Sequencer

Newsgroup: rec.radio.amateur.homebrew

From: Robert Offer <robert@g1zjp.freeserve.co.uk>
Message-ID: <ah207t$4om$1@news7.svr.pol.co.uk>
Source record: 42686

Hi all,
I have a sequencer which has developed a fault. It looks like a kit which has been built by a former owner.
The PCB carries the etched characters CA printed on it and has positions 1-4 also etched onto the board -switched inputs/outputs. I suspect that the problem is probably in one of the two ICs which the unit uses. There is the heart of the problem, I have contacted RS technical and searched the net and can't find any info. Any suggestions, please? The references are:
RCA - CA339E
and
40308DC this chip also carries the number 8112
All sensible ideas very welcome
Thanks in advance
Bob

1174. ISO: "Squashed Bug" construction technique info

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-16 20:49:38 UTC
From: "Joseph A. DiVerdi" <diverdi@xtrsystems.com>
Message-ID: <diverdi-B31A57.14493816072002@europa.frii.com>
Source record: 42687

I'm searching for background info (citations, URLs, etc) on an electronic construction technique
known as "squashed bug". I believe that I did see a reference to this technique in an old ARRL
Handbook but can't be certain.

For those unfamiliar with this technique, it gets is name from the flattening out operation performed on ICs which are then attached (glued and/or selectively soldered) to a PC board (bare or
copper-clad). Often the flattening out is more accurately described as splayed out and it looks like
a cartoon drawing of a squashed insect.

Any reference info including pictures and/or descriptions would be greatly appreciated.

Best regards,
Joseph

Hi Bob
The sequencer is almost certainly the one published in several ARRL
handbooks, for instance on page 31-9 in the 1992 edition. It is designed
by Chip Angle, N6CA.
This should ease your search, but I can easily copy/scan the pages for
you if you need it.

It depends on how much else you know, I suppose... For example if the
miniature FM trnasmitter uses an MC13175 chip, the data sheet will
tell you that you can get up to 10 milliwatts out of it. If the
circuit has a tank in the output, you might try assuming a load that
would result in loaded-Q of 10 or so and estimate the power from that,
assuming the RF swings 2 times the DC applied, peak to peak. But as
they say, "YMMV" ... considerably in this case. Why not just build it
and measure it? Sometimes you can do that faster than you can
unscramble all the confusion in an incompletely documented design.

Cheers,
Tom

The first thing to do is explain what M-magazine is or the rest of the world is all floundering about in the dark as is usual in these careless, ill-written-to newsgroups.

1179. Re: RF Output Power from Schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-17 00:36:57 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ah2e79jtf1@venus.btinternet.com>
Source record: 42692

RF output power is the peak volts (minus 1 or 2) squared, across the transistor collectors allowed by the DC power supply, divided by twice the load resistance presented to the points between which the peak volts occur.

Watts = Vpeak-squared / 2 / RloadOhms.

Where, it should be repeated, Vpeak is set by the DC power supply voltage.

And if you are unable to understand this simple relationship then you have no rights to be designing the circuitry.

On the other hand, practically anything will work after a fashion. There are many so-called professional designers who manage to make a living out of "anything will work after a fashion.". But they are no more than confidence tricksters obtaing money under false pretences..

It's a cruel world isn't it ?

A superbe synthesis of the "ugly" and "squashed" (or "dead") bug schools
appears at http://www.qsl.net/ke5fx/tr503/110syn2.jpg. :) The DIP
packages have had their through-hole leads cut off and their tabs
flattened out, except the ones that go to the ground plane.

If you search on "dead bug construction" you'll probably find a lot more
examples. I don't think I've ever heard it called "squashed" before.

A horribly ballpark figure is to look at the specifications of the
output device - that at least will give you its theoretical maximum
DC input. From there, assuming its Class C work out the max. possible
output power. But as a previous posting said, unless you know the
antenna impedance etc. anything more than that is pure speculation.

Well, for an RF amp, 50 ohms is a pretty good guess most of the time, the
tricky bit is reflecting that back through the output network to figure out
what impedance the transistor is seeing.

Does anyone know or know where to find the protocol used by the IC T7H to communicate with it's remote control mike.

I was looking for a microcontroller project for my classes and thought building a remote control for this might be fun.

I asked ICOM and the denied any knowlege, Interesting comment.

I prefer the dead bug method where you tack an ic down with rtv or
something similar and then leave the legs up where you can wire wrap to
them or fly leaded parts to the legs and tack solder.

If you want high frequency and good mechanical performance, then make a
two sided pcb (FR4 1.57mm thick) with solid copper on one side and small
pads at 2.54 mm spacing on the other side. If you place a few 2.54mm wide

buses on this side, you can also use these for B+, B- or 50 ohm microstrip lines. This last technique I used to use all the way to 900 MHz with no problem, but I also used some homemade via's strategically placed along with good grounding from the copper side to the buss/pad side. At Motorola in Plantation, FL we called this Z board and had it kept in the engineering stockroom. This works great for digital work also even at the 100 MHz or higher clock speeds. I would finally suggest that one of the busses be a continuous 2.54 mm wide buss all the way around the outer edge of the pad/buss side. This makes it easy to get a good ground from the solid side to the top side through copper foil or other conductive means (straps, wires, etc). I would normally draw a picture, but I don't have any drawing tools any more. Happy trails.

1188. Where Can I Find Power Connector For Kenwood Mobile???

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-17 05:14:53 UTC
From: xtx99@aol.com
Message-ID: <20020717011453.26138.00000135@mb-mj.aol.com>
Source record: 42551

Any help on where I can find this connector is appreciated (it's the power cord that connects to the other half of the power cord that is attached to the Kenwood dual band TM-G707A mobile 2 m/ 70 cm radio). I would prefer to just purchase quick disconnect female terminals, crimp them onto 10 gauge wire and insert them into this connector (instead of splicing them onto a power cord with the wire and quick disconnect female terminals already attached). I have placed 2 pictures of the connector on my webpage (http://members.aol.com/xtx99/index.html)and would appreciate and suggestions. Radio Shack didn't have it. I'm saving the original power cord for base operation and temporarily carefully inserting disconnects into the connector for mobile operation (thank God for fuses!!) Thanks

1189. Re: RF Output Power from Schematic

This makes assumptions about the waveform. I've made class C amplifiers which put out about 7 or 8 watts that have a peak voltage of around 35 volts when using a 12 volt DC supply. I doubt that the load presented to the transistor is purely resistive. Efficiency of these is typically around 85%.

But I'm afraid I'm one of those who have no rights to design such circuitry, since I don't know where the "simple relationship" comes from and what assumptions must be made for it to hold. Do you?

Hi Derek

Your methods and results make sense. The ICS1702 chip used in my homebrew charger (and possibly others as well) does an automatic 2-hour top-off after the fast charge. In addition to that, I have built a PIC-based front-end running automatic sequences of fast chg - top-off chg - discharge until the discharge time does not increase any more. In my experience this does a very good job for conditioning cells which idled around unused for several years. Normally it takes between 3 and 6 cycles for the capacity to saturate.

Al, if you can find out what the DC collector current of the PA might be, another way of estimating RF power output is to assume the PA is around 60 percent efficient (on FM at VHF), then Pout = 0.6 of DC supply volts times DC collector current.

The power rating of the output transistor might provide an additional clue.

On the other hand, if you only want to alter the power output to suit your own application, just copy the circuit and use a transistor of appropriate power rating.

So just order the connector and pins from Icom, both are available
without the power cord.

==========
In connection with the above it is perhaps useful to highlight availability
of the 'island' cutter ,also called the NJ-Islander ,as supplied through the
New Jersey QRP Club and in the UK through the G-QRP Club.
This rotary diamond tipped end mill (used with an electric drill in a
stand)with a shaft of Dia 0.125 inch,cuts islands of Dia 0.2 inch in pcb
leaving copper islands of Dia 0.14 inch.
A superb way of making RF circuits with only very little copper being
removed.

I have a really nice BIG transformer. GE model 81g465 rated 1.1KVA. 115v in 4620kv@750miliamps center tap. so that would be about 2310v x 2 @ 350 miliamps this baby will pull 2 seperate power supplies @ 2.5kv. Will pull like 2 4-400A or 2 4-800. weighs about 65 or 70 lbs really nice. Looking for offers on this ....Can ship if i have to. Location North Carolina
http://chris28681.tripod.com/ here are some other items i have for sale..

Exactly 1/10inch or would 2.5mm or even 2mm or 3mm be OK ? :)

I'd check www.powerwerx.com for a proper connector to make an
adaptor to anderson powerpole. Or else (after factory warranty on
the radio is gone) replace the factory connector with powerpole
connector. (I'd preserve the factory connector and perhaps even put
powerpole on it also, so I could connect the radio to a factory
power cable if so desired.)

Hi,

Probably there is something wrong in your description.
If my math is right that transformer should be rated 3.46 megawatts :-)

Peter

0.1 inches is the spacing of DIP components, so it would be a good idea to stick with that spacing. The larger SMD components have a 50 mil pitch between leads.

Anyone have any knowledge of the EB63 2-30MHZ amp. sold by Communication-Concepts? I'm thinking of building one once I get an FT-817. I would like to hunt for my own parts but I don't know how to etch a pc board. Comm.-Con. sells it as a full kit for $102.60 w/shipping w/o the heatsink. Is this a good amp? What do I need to etch my own boards? I have a photo mask for the layout I need for this amp.
Thanks, Damon KC5CQW

It's a fine amplifier, although it's getting a bit long in the tooth by now, I've built several and not encountered any problems with them. Order a couple sheets of PnP Blue from Techniks in New Jersey, and follow their instructions for the board. I believe Brad Thompson still has some suitable transformers. If he's out, get back with me and I can fix you up with one. FeCl4 available from Radio Shack.

> 5.0000MHz .56uV
> 10.000MHz .36uV
> 20.000MHz .38uV
> Falls off from there but thats ok, I generaly stay in the 80/40/20 meter bands

That is abysmal performance for a so called "excellent" receiver.
See the QST product reviews for the numbers I posted below.
http://www.arrl.org/members-only/prodrev/bymfg.html

Per the product reviews:
For a circa '80 Kenwood TS 180, sensitivity is .25uv
For a circa '85 ICOM 745 sensitivity is less than .15 uv
For a circa '90 Ten Tec Omni V sensitivity is .15 uv

For a circa '95 ICOM 736 is less than .15uv

Clearly, we are talking about two different things
when we say "excellent receiver".

We do agree on one point you made:
"the best part of the hobby," (is) "HB, scrounging, and putting
forth as much effort to learn the dark art of radio as they have
time for."

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 21st 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

1214. antenna for HT

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-18 16:22:12 UTC
From: Matt <mthomas@biocontrolsys.com>
Message-ID: <ujdqic17rg8v03@corp.supernews.com>
Source record: 42576

I want to build a 2m/70cm J-pole that I saw in QST a couple of years ago. I'd like to be able to use it with my IC-T7H handheld. Will I need to build/buy some kind of antenna tuner for this to work, or will it work better than the whip without that? Or will it cause the HT to explode/melt/fry/etc?

Thanks,
Matt

1215. Re: antenna for HT

1216. Strange oscillator.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-18 21:16:15 UTC
From: JCM <menardjc@wanadoo.fr>
Message-ID: <ah7b85sb2@wanadoo.fr>
Source record: 42579

I have built the following oscillator found at:
http://jnaudin.free.fr/cnr/negosc.htm

```
+ --1 k resistor------A--------II--------------
220 pF C
12 Volts O
I
L
- ----------------------B-----------------------
```

A: to emitter of a 2N914
B: to collector of the 2N914
Base of 2N914 not connected
Coil is from a 455 kHz IF transformer
Result: 300 kHz sine wave.
Max frequency with a smaller coil 1.8 MHz

All transistors are not equal:
2N2222 ok up to 100 kHz max with larger capacitor and coil.
BF245 and many other BF... do not oscillate.
PNPs reverse connected do not oscillate.

How can this "thing" oscillate ? some kind of a "tunnel" effect ?
Nothing found in available semiconductors literature.
Thanks in advance for an explanation of this mystery.

JCM

JCM, there's no mystery.

Stop worrying about an open-circuit base. Your circuit is not breaking any fundamental laws of physics.

No device is perfect. There are ALWAYS internal leakage resistances and capacitances, inductances even, which you are not showing on the complete circuit diagram.

Complete the circuit. Don't forget to include the input impedance of the oscilloscope, or whatever measuring instruments you use, and you have an oscillator.

Sometimes they oscillate and sometimes they don't. It all depends on circuit and transistor imperfections.

Some people call them parasitic components.

Just design the circuit properly, take parasites into account, lump them with the others, and you won't have any problems.

Message-ID: <3d37511d.78253148@news.tn.comcast.giganews.com>
Source record: 42581

All,

I'm in the process of putting together a simple wire ground plane antenna for 144mhz (ARRL antenna book, 18th Ed, p18-17, figure 25).

The verticle element is 12g copper wire, and is straight in the book, but I'd like to put a loop at the end so I can hang it in a tree outside the bedroom window.

Do I need to trim the wire to length based on the length of the wire from connector to top-of-loop, or is the actual length of the wire (even if looped) what's important? I hope I asked that well!

TIA, and 73

Anthony

1219. Re: Strange oscillator.....

Source record: 42582

Hi, The 2N914 is a fairly vintage transistor it was around in the early 1960s. I think it was one of the first Fairchild commercial silicon planar devices. I know we at the Post Office ResD at Dollis Hill did some reliability testing on them for use in submerged cable systems

I suspect it may depend on the manufacturer of the device, and even then not all 2N914 will necessarily oscillate. The 'reversed' transistor is operating in 'avalanche mode', which has a characteristic like a neon tube, with hysteresis between the switch on and switch off points. If you replace the the C and L by a short piece of open ended coax you will get a very narrow fast pulse, possibly only a few nsecs wide, with very fast edges. It is an ideal harmonic generator., and were used in the 1960s as sample pulse generators sor sampling oscilloscopes. The base is usually biased in these circuits but it could be that it will work open. Ferranti used to make devices specially for this service and I think that their 'alter ego' now called Zetek still do. More modern transistors since the advent of epitaxy, may have higher avalanche voltages than 12v....try them with say 24 volts. Ian Hickman has written an article in Electronics World (the old and much more famous Wireless World) a couple of years ago, and covers the subject in one of his books.

I would suggest using an insulator of some sort between the antenna and
the tree!
If you loop it and CLOSE the loop the overall dimension should remain
very close. I'd knock off about a quarter inch just based on gut
instinct.

Sorry, I should have mentioned I would be using a closed loop. I
suppose a more accurate question would be: Is the radiating length the
length overall, or the length of the element wire?!

Thanks, Bill

I've got a design that you could fit into a car radio chassis, but you could count on at least 100 hours work to complete the job. It runs on anything from 12 to 15 volts, and it is a general coverage design. Unfortunately, I don't have any more PC boards to send out, but maybe the design will give you some ideas.

Nope. Been thru it with a fine toothed comb. Not even any jumpers to restrap. Maybe different pin connections to the chip would do it but I'm lacking any info. I've seen some that have a special key-punch procedure to switch 'bands' but I've not hit any magic combination.

Has anyone (particularly in the UK) construcuted one of these designs or considered consrtucting one? I am particularly intersted in the G4PMK design as featured in Radcom and the RSGB book "Test Equipment for the Radio Amateur".

My RF experience is very low, but my digital is very high. I have a number of satellite tuners. They are digitally controlled using a I2C bus. They are used to tune 950MHz to 1350MHz. I was wondering whether I could modify one in some way. Is it possible to convert 0->100MHz (say) to 950MHz->1050MHz with a circuit that can be constructed by an amateur? Perhaps I could use a second tuner to generate the 950MHz mixer frequency. Software could be used to scan the band. Since the tuner is a digitally controlled PLL, the accuracy should be very high.

A great help is that I have the schematics of these particular tuner modules. Following the mixer is a 495.5MHz SAW filter with a 32MHz bandwidth. There is then some more circuitry which includes a 495.5MHz oscillator, which I assume is some kind of mixer. The final output is I and Q. These outputs are normally used for the QPSK demodulation. I assume that I will need to add the same kind of filter and log amplifier in order to find the signal of interest?

If anyone is interested in this area, please get in touch. I have a spare tuner if someone is really interested.

regards...

--Gary

I sounds like a pretty cool radio. I wonder what chipset it uses. Motorola had the MC13030 dual-conversion AM receiver on a chip, that was aimed at the auto radio market for awhile, but unfortunately, they discontinued it. A shame, because it was a good chip. I built a MW radio based on that design, and it was a winner.
I think Phillips also had a chipset aimed at the auto market. I wonder if your radio is a dual-conversion design.
Anyway, your price sounds good. If you want to sell it, I can send you cash; just e-mail me directly.

I've been using the AD9851 for awhile. The unit has a 30MHz tuning range, and the display always shows 0 to 30MHz.
You can tailor it to any I.F. just by entering the offset in the hard code. If you have a 45MHz I.F. and enter that offset, the DDS will tune from 45 to 75MHz; if you enter a 10.7MHz offset, the DDS will then tune from 10.7 to 40.7MHz.....and so on.....
I would be glad to send details of this synthesizer to interested parties, including the source code and the hex code. Jeff Woods, formerly of Kachina wrote the code.

I took off a couple covers to try and answer your chipset question but I'll bail from further disassembly given that the radio is now sold...fortunately to a chap in the UK where the 9kc split won't be an issue.

This radio is from St. Kitts, the local dealer there (TDC) imports directly from Japan generally requiring cars with Left-hand drive and English gauges. Miles instead of km on the speedo, for instance. Radio be damned.

Quite a few of these radios show up as 'surplus' given that the two main local stations are on 555kc and 895kc. The problem is catching them before they hit the trash barrel.

No doubt there is a way to reprogram the thing, and my bet is that it can be done thru a button sequence but I have not been able to do so.

If you seriously want one, I can alert my 'car teefing' buddies to find another one.

Regards, Bill

G4PMK regards that design as obsolete, but unfortunately can't prevent
RSGB from re-publishing it.

For a modern and much improved design, search the web for W7ZOI's pages.
His article about a spectrum analysers and accessory tracking generator
was published in QST, but there's probably more detail on the web.

I'd be interested, however, 32 MHz is too wide
a bandwidth - you might as well use an Abortion
Wavemeter!

With that tuning range, an even better analyser covering
up to 400 MHz is possible.

I suspect that a problem will exist with the synthesizer
being programmable in steps the size of the channel spacing
which for an HF analyser might represent several harmonically
related bands.

We are *still* building a DDS/PLL LO which would be suitable for such an analyser. John Miles is in the process of writing up the results
Frequency is digitally settable to 1 Hz or better with step times less than 1 msec. Freq span is 1-2 GHz for the current components though others could be substituted for other ranges from about 100 MHz to 2.5 GHz. Phase noise performance is good for such a simple oscillator. There have been a few problems at close to multiples of the DDS clock frequency with sidebands appearing - esp at near 2 GHz. However this could be got around by varying the DDS clock with software You could drive a ring diode mixer followed by a roofing filter at 1000 MHz or so and you would have a front end for a receiver/spec analyser for 0-800 MHz or so.You could follow this with your tuner as the 2nd IF. I suspect the tuner frequency step size may be quite large which would restrict its frequency resolution as a front end.
An alternative scheme might be to use the DDS/PLL board as a 2nd LO with fine freq steps to mix the output of the 495.5 MHz filter down to a lower IF where narrow filters could be used to give good frequency resolution.
You could follow this with an Analog devices Log amp. Finally a PC could be used to drive it all and display the results. It would be an interesting project but not a trivial undertaking! Perhaps a group could be formed to work on it cooperatively.

See http://www.qsl.net/ke5fx/synth.html
for details of the DDS/PLL board

Talk of a device that's way ahead of it's time.....GPS receivers still need a clear view of at least part of the sky, don't they? Think the kids will stay out in the clear all the time? And the whole world sure isn't wired for PCS yet, by a whole lot. But it's a neat little device. Problem is, it produces raised expectations which aren't likely to be realized.

Message-ID: <4huijugol0faf7v6te1t1ph1pen811ovit@4ax.com>
Source record: 42502

I'm wanting to build a device that accepts two audio outputs (scanner and transceiver) and puts it out to one speaker. Some kind of audio mixer would work, but what I think would be even better would be one in which the scanner gets muted when the transceiver receives, a mixer with a priority. I need this to be relatively small, as it will be in my car. First off, does anyone know if something like this is produced commercially? Second, if not, can anyone give me some pointers on how to accomplish it? A mixer should be fairly easy, but the priority idea I'm not sure.

One disadvantage of having both come from the same speaker is that you'll have problem figuring out over which radio the message you just heard came over.

I'd suggest thinking about simply placing more then one speaker in the car in such a way that you know by the direction which one is which.

The mute is a good idea. It shouldn't be too hard to build. It's just a vox circuit that runs on speaker leads instead of mic. But once you'd used a relay to open the speaker, it would be a minor detail to use the relay to switch signal sources.

No.

I have a new standard that is far above anything I own already, or have built.
It will meet my needs for years to come.

Someday I may have access to a GPS receiver, and desire to understand the
principles in the required comparison. It is the method I want to explore.

That is all.

When you build an electronics project that uses LEDs, how do you mount these devices? I find LEDs tricky to work with, because those leads are long, uninsulated, and fragile.

I would like to hear your favorite methods.

I used a system in a Van Mobile some years ago that worked well..Take a good sized toroid ,1 1/2 inch diameter or so , put three equal windings equalley spaced ,about 10 turns each ..one to spkr one to BC radio one to scanner radio..set the scanner volume higher than BC ,when squelch opens it will over ride BC enough to be heard.Not perfect but it worked for me. good luck,,

One of:

Use glue (Hot melt glue is very easy to work with).

Use a led mounting cap (Also easy to use).

Use a led lamp that can be mounted (Very easy, but at a price).

We most always mount them on a PC board which is in turn bolted to the
box or panel. Ideally this is the main board in the system, but if
that's not practical, we do a little auxiliary board (with pushbuttons
or whatever as needed) and connect that with a ribbon cable. If you're
building by hand, you can use some sort of proto or perf board, solder
the LEDs to that, and run wires or ribbon cable off the board.

The other thing you can do for one-offs is wire-wrap #30 insulated
wire to the LED pins. That avoids soldering and lead stress.

They make something like that for private arcraft pilots. It allows more combinations than you need but the circuits would be the same. The one I saw a few years ago only had a couple basic ICs. I think there is an IC that is a mixer and onother that provides attenuation or volume control with the mute built in. The purpose of the box I saw was to allow the pilot to talk to his passengers headsets via open mic but when he keyed his transceiver mic the passengers were muted. There was a short time delay and even a stereo input jack so you could listen to CD player, but transceiver audio instantly muted stereo then when then transmissions ended the stereo would fade back on to the level it was at. If I find a schematic I will post it.

Another method that can work in a pinch is to drill a hole in the chassis
that the LED will fit in snugly, and then apply a drop of superglue to the back.
While this is not very "professional", it does work and is okay for hobby
prototypes or "one-off" items.
My preferred method is the plastic LED mount that comes in either one or two
pieces. The one piece models click in through the front and the LED clicks into
the back pretty securely by flaring out the four tabs.
The two part model clicks into the front of the panel in the same manner,
but once the LED is in, the plastic collar snaps over the back and securely
holds everything in place.

Cheers!

Hi Richard,

the tuner lo goes from 1430 to 1930MHz. Step size is 62.5kHz, but I wonder if this can be changed by changing the 4MHz reference xtal to something smaller.

There is a second mixer which takes the 495MHz +/- 16MHz signal band and mixes it with 495MHz phase shifted to give the I and Q outputs. My understanding is poor, but I wonder if I can just put the I (or Q) output into the 10.7MHz filter and following circuitry as described in the low cost spectrum analyser? In this way I would be grabbing just a slice of the spectrum.

I know the tuner works great as a spectrum analyser when connected to a standard LNB. I have plotted in software a graph of frequency vs AGC for Astra in order to see the transponders. This is when the tuner is connected in its standard application to a QPSK digital decoder chip. The AGC value can be read in software.

The oscillator is unfamiliar to me(!). The oscillator transistor is in emitter follower configuration with a small C (1pF) from C to E and E to

B. The tuning coil is a stretch of PCB track about 2mm wide and 1.5cm long (curled up a little). There is a varacter tuning diode at each end. If I cut this track and attach a very small loop of wire (to make the inductor longer) what's the chance that it will still oscillate. I calculate that the current inductance is around 1nH, does this make sense given the dimensions?

Can anyone identify this type of oscillator so that I can do a google search for information?

I was hoping that I could change the oscillator to run 500MHz upwards. Perhaps losing a gig at the bottom end is asking too much!

input 0 to 500MHz (via LPF)
\
+--> 495MHz IF (32MHz BW) \
/ +-> 10.7MHz IF --> demod/log
AMP.
/ 495MHz fixed LO ---- /
/
/
digital local oscillator (500MHz-1GHz) <- I need to hack the LO

Is this feasible or have I made a fundemental mistake somewhere?

I have a 50MHz scope and a 600MHz frequency counter. Can I use these bits of kit to measure (even see if it is there) the tuner lo at the normal frequency range? If I can measure the lo (in some way) as it stands then I should be able to check whether it still oscillates when I hack the inductor.

Anyone in Bristol who is interested in microwaves???

regards...

There are plastic hole inserts that you could use, or a fancy metal holder,
both can be found at Radio Shack.

I built a hyperdrive so I could travel to Uranus.

I used the little plastic LED mounting grommets for the hyperspace field inverter stability indicator. The voice coil and spatial alignment matrix next to it was, of course, an issue, but the LED faired well.

Even though a high-output dynamo was near causing an inverse spatial field flux, I was able to get it in the aux. plate using a cordless drill and a small bit.

Umbriel is wonderful in the spring.

Hi Fellas;
I have for SALE:
Like New(mint), Heathkit IT-11 Capacitor tester.
I checked the manual for the parts & they are all there except the Fuse holder & a few resistors.
The Fellow became a SK but not until he started on the kit, well just about!
He only started on the chassis components, really nothing soldered to speak of, he just started.
I did'nt bother counting all the little screws as they were in a bag & would have taken hours :-)
Everything else, Transformers, switches, sockets, knobs, etc has been accounted for!
Price is $200.00ppd or B/O, Conus.

I have used a black rubber gromment that fits the led package snuggly. Drilled a hole in the chassis, mounted the grommet into the hole and placed the led in it.

I sometimes cut the leads to about a half inch and solder wire to them with about a quarter inch overlap joint. Then put heat shrink over the joints. (Yeah, you have to put the heat shrink over the wire first then slide it on. Unless you have some of the 4 dimensional wire that you can slip on after the joint is soldered hi hi)

For PCBs, I like Manhattan style construction. I glue a couple of pads to the base PCB, cut the leads of the led to about a half inch and bend a foot on each lead. Then I solder them to the pads. (Remember which lead is which as many leds show their polarity by having the plus led a little longer. I generally check to make sure I have the right polarity at the time I mount them.)

Hope this is of some help.

<snip>

Call me picky, but my favorite is the Dialco mounts with the
cartridge-style LED lamps. They come in a variety of input voltage
ratings, all with a built-in limiting resistor, and you can make use of a
given voltage rating on a higher input simply by adding another resistor.

I do, of course, realize that this is one of the most expensive
ways to go about it IF the materials are purchased at the new/retail
level. However, I'm fortunate to have a good local source for surplus
pieces.

I was there myself testing my bicolored LED indicator which lets me know if either my Tachyon Field Inverter is about to collapse - or if my eggs are hardboiled. I used a quick two-part black LED clip which securely mounts it into a suitability sized hole - which is far better than super-glue or blue-tak which can become unstuck as you pass the asterioid belt and it gets a bit chilly. (Blue-tak tends to peel away at low tempreatures or when the cockpit becomes steamed up when you are cooking your dinner (hence the bicolor LED)!

Un evento particolare per il prossimo 23 Luglio: dopo l'incontro di venerdi
in Firenze,

marted&#65533; p.v. si terr&#65533; un incontro alla Villa Medicea di Coltano (PI) tra il
Ministro

M. Gasparri, Ministro per le Comunicazioni, le rappresentative locali,
esponenti del mondo tecnico scientifico, con la Signora Elettra Marconi,
figlia di Guglielmo, madrina dell'evento, un dibattito dal tema "Coltano,
riaccendiamo il segnale, proposte per il recupero del centro radio e del
centro produzione RAI". Coltano, infatti, e' rimasto l'unico luogo al mondo
a versare in stato di abbandono, tra quelli che hanno fatto la storia della
Radio e di Guglielmo Marconi.

Per l'occasione le sezione ARI di Pisa attiver&#65533; una stazione speciale, dal
nominativo IY5PIS,

dalle immediate vicinanze del centro marconiano dalle ore 15.00 locali; le
frequenze preferenziali

saranno 7.030 (CW), 28.470 (FONIA), 14.270, 21.270 (FONIA) sperando in una
propagazione favorevole per collegamenti a lunga distanza.

Una stazione packet sar&#65533; allestita per monitorare la attivit&#65533;.

Altre "stazioni marconiane" hanno aderito a questo evento (KM1CC, GX0MWT,
IY4FGM, VO1MRC, VO1AA, GB2LD, GB2GM.) e garantiscono la loro presenza in
frequenza per il pomeriggio del prossimo 23 luglio.

Un ringraziamento a queste e chiunque altro collega che vorra' contattarci.

A presto,

Paolo IK5ZTT, ik5ztt@amsat.org

Engaging that hyperdrive must be a real kick in your anus!

If you don't like messing with mounting LEds to the enclosure, then you can do it like a lot of equipment has it done recently. You put the surface mount LEDs on the circuit board, and then use a short length of clear plastic rod to pipe the light to the exterior of the enclosure. In one case, the Cisco IP phone, when the phone rings, the earpiece of the handset flashes bright red. I said to myself, how the hell did they get the handset to light up when, like every other phone, there are only four wires to the handset? Upon closer inspection I found that the handset has a piece of clear plastic thru the earpiece, and the LED is in the cradle of the base unit, and shines _thru_ the handset.

Sort of like Warp Drive!

You might be able to get step size down a bit by reducing the reference
freq. Bear in mind however that the loop filter will be designed with (among
other things) the reference freq in mind - so reference sidebands may become
a problem. I assume it is a single loop PLL - in this case there is a limit
to the minimum step size set by lockup time and the loop filter. Also you
would have to change the main divider ratios in software

The I and Q outputs will have to be 90 degree phase shifted relative to one
another (they are already in phase quadrature)
and summed to give a single sideband output. Otherwise you will get an IF
image at +/- 10.7 MHz from the carrier (21.4 MHz from your wanted signal).
The 16 MHz bandwidth filter is not going to give adequate attenuation.
You could do this with a phase shift circuit at 10.7 MHz (eg a 2 section
polyphase). Opposite sideband suppression will depend on phase and amplitude
accuracy in the front end. I would think it would be difficult to achieve
more than 40 dB suppression at these frequencies.

The AGC is quite a good approximation to a log amp in many systems - maybe
you dont have to do any more!

I have often used a small piece of MiniMount (Selfadhesive PCB strips)
I put it close to the hole and bend the LED pins back and solder them on
the pads. It can also carry a current limiting resistor etc. if needed.

Looking at the original web page, I can safely say that I've never seen a
more obfuscated explaination of operation since De Forest's
non-explaination of the vacuum tube. How does one get negative resistance
in the low voltage curve of Vceo? It eventually will get low resistance
at or near breakdown, but up to this point, current is slowly increasing

and eventually the resistance will go low, but not negative or am I missing some portion of this discussion?

I have been looking at the schematic below to try and understand what is going on. It is a baby monitor
transmitter. It's basically a mic amplifier with AGC, a modulator, and some kind of RF output section. I'm
only interested in the top half of the circuit, the modulator and PA. Could someone give me a brief overview
of what's going on? I would really appreciate any help. BTW, what are the FT129 and FT130?

You can use a small 6 or 12 volt filament transformer as a temporary fix.
Despite what others may say about core saturation -- it WILL work.

What lead did you cut short? If the secondary, peel back the insulation
and find the lead -- should be about 18 gauge enamel and easy to
splice.

There's a neat trick used in the mounting of the direction-indicator LEDs in the Ramsey Electronics doppler direction finder kit. They're simply soldered to the main PCB, with fairly long leads which carry them up to the front panel. The plastic panel simply has holes drilled in it. No clips or adhesive are used.

Getting all of the LEDs mounted at exactly the same height above the board (an inch or so) would seem to be a nightmare, but it's actually easy. You drop the LEDs into the PCB holes (checking the polarity, of course!), then put the PCB temporarily into position into the top side of the cabinet. Holding the two together, you turn them over... and the LEDs drop down and (with a little bit of wiggling) drop into the holes in the cabinet top. The raised rim around the base of each LED stops them from falling through the front panel. Voila - they're all in position, and perfectly aligned. Solder the leads to the PCB, clip off the excess, and you're done.

It's a slick trick - less expensive than using clips (allows for a more compact pattern of LEDs, too), less messy than hot glue, and much easier than trying to adjust the LED heights by hand. It should work in any situation where you're mounting a bunch of LEDs, and can manage to have a PC board in a reliable position an inch or two behind the panel.

What you have here is a very simple FM transmitter.

Q2 is a Colpitts oscillator controlled by crystals X1 or X2, selected by SW1. Varactor D1 and inductor T3 along with mislabeled R8
(should be R6) are the FM reactance modulator circuit. The capacitance of D1 changes with varying voltage applied via R7. Voltage
divider R8/R9 (near the op-amp) sets the DC offset of this voltage, setting the unmodulated frequency of the oscillator, and the
audio signal shifts this voltage applied to D1 above and below the DC offset point, changing D1's capacitance and hence the
frequency of the oscillator. The unmodulated frequency will be below the crystal's self-resonant frequency.

Tuned transformer T2 couples the signal generated by Q2 to the next stage, and most likely is resonated at a multiple of X1 or X2's
frequency by C4. Its main purpose is to filter spurious signals generated by the oscillator. T2's secondary winding is coupled to RF
amp Q1 through the small value (6 pF) capacitor C5. BTW, there are two C5's in this schematic. The 100nF C5 is a bypass capacitor,
and along with R3 reduces the amount of RF transferred to the DC supply line. Capacitors C7 and C8 are the RF feedback network for
the Colpitts oscillator. R4 provides emitter bias and R5 provides base bias for Q2. These two resistors set the DC operating point
of Q2 for proper operation.

Q1 is configured as a common-emitter class C amplifier, with operating bias set by R1. The output of Q1 is filtered by resonant transformer T1 (along with C1). T1 also acts as an impedance matching network along with L1
to couple the amplified signal to the antenna. C2 and R2 provide the same function as C5 and R3 described above.

1277. Spice model of BFY90 wanted?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-21 23:33:52 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3D3B459D.A2DE4D7B@alma.demon.co.uk>
Source record: 42540

Has anyone got a spice model of this transistor?

It appears to be obselete, however it is used as the front end in an UHF prescaler kit from Maplins. I am interested to check theory (using spice) against measurement (using kit at work). It's part of my on-going experimentation.

Actually I am trying to find a design of a high impedance amplifier which will take a few 10's of mV and turn it into a signal to drive a LS logic gate input. I'd like it to work upto 60MHz (lower limit is not too important). The Maplin design may be a starting point for a new design.

regards...

One tip when mounting leaded LEDs to a circuit board -- make sure the hole spacing is the same as the lead spacing. Bend the LED leads before soldering if necessary to make them match the hole spacing. The reason is that soldering softens the LED plastic via heat conducted along the leads. If there's any stress on the leads when you solder them, the LED can be internally damaged. Sometimes this doesn't show up as an immediate failure, but as a shortened LED lifetime.

If I were to build a transmitter similar to the one shown in this circuit, what would be the best way to stop
it transmitting entirely from a 5v CMOS uC and why? Would it be as simple as adding a FET or relay between
the power supply and transmitter or is there a better way? What impact would this have on normal operation?

Quadrature does mean 90 degrees relationship (thouigh for the strict
mathematicians it means orthogonal in the linear algebra sense I think - no
doubt I will be corrected by someone)
This is the basis of a phasing SSB generator or receiver
The first 90 phase shift of one signal path relative to the other takes
place at RF and the second at baseband. This can be done by an analog
circuit (eg passive phase shift circuit) or digitally (eg Hilbert transform
in DSP) The reason that one sideband is cancelled is that the audio or
baseband from the two sidebands is phase inverted, one relative to the
other. Thus one will add while the other will cancel when they are summed.

This scheme seems to be widely used in microwave systems to allow either
direct conversion to baseband or suppression of an IF image.

ISTR that Hilbert transform in DSP is for the
second half of the impulse response to be the
inverse and time-reversed mirror of the first half.

Similar to a linear phase filter where the second
half is the time reverse of the first half?

I would recommend that you use a differential amplifier ic from one of the IF ic's now in production as they have loads of gain and don't do funky things when the stages start clipping. Don't think that you can get good clipping performance from a single xsistor stage. There is a reason why limiters in the FM IF backend ic's were differential amps. Look on the vendor pages for Motorola, Philips, Siemens, Hitachi, etc. For the input to the amp, you could use a high freq voltage follower or JFET source follower with the correct freq response.

Oh dear, I really should have proof read my rambling prior to posting
:-(.

for "mantion" read mention
for "later one with mods" please add the word 'had' after mods(not
good english.. but there you go)
For "Aditional" please read Additional

this post also probably not proof read.
Many apologies.. a mere M3

Hi gang,
I am looking to build a keyer. Here are the requirements:

Non-pic based (nothing against a PIC, but I want to use descrete chips,
ie., RS JK D type 555 etc)
Non Curtis chip based (see above)
Dot memory
Self completing
Adjustable speed and weighting

Any sites you can recomend?

Thanks

Look for the WB4VVF Accu-keyer which is a late 1970's keyer. I built one around 1979, my first ham project, and I am still using it and it works great. I built the "deluxe" version which had 4 memories and a LED display showing which memory and it's content count and was 4 PC boards. The keyer board, the memory board, the display driver board and the front panel LED and switch board.

In fact, somewhere I have another set of boards almost completely built. Plus, while helping to clean up the club shack last weekend I found a complete set of bare boards for it. Nobody else knew what they were.

Can't remember if keyer was a QST or Ham Radio Magazine article. But, maybe you can find reference to it on the web.

Shouldn't be to hard to build the actual keyer as it was all 74xx TTL chips. But, the memory part may be a problem as it used old, then new, technology single bit, about 4 of them, static rams. They may be hard to find now days.

Can't find my old schematics, bet it was in a magazine that is now boxed up and buried in the storage shed out back ot thrown away.

Good Luck...

For those interested in Amateur Radio Experimentation, there is a new club, the Amateur Radio Experimenter's club, in Reading, MA. There will be a meeting this Wednesday, July 24, at 7:00.

The experimenter's club would be open to anyone interested in electronics, any licence class, or unlicenced welcome. Hams, students, professionals are all welcome to join. If you are in the area and are interested in such a club, you can email me. If you have any questions, you can post them to the forum.

The purpose of the club will be to work on circuit design projects, antenna setups, radio measurements, radio direction finding and other aspects of Amateur Radio experimentation.

The meetings are tentatively held alternate Wednesdays at 7:00 at 49 Pleasant St., Reading, MA.

The meetings are at the 49 Pleasant St (Reading Senior Center), Reading, MA

Here are the directions to the Reading Senior Center:

Merge onto I-95N
Take exit 39- RT 28 Reading, Main St
Merge onto RT 28, Main St.
Keep going straight, see Mcdonald's on right side
Keep going straight,
You will see a big traffic light pillar in the middle of the road.
Take a right onto Pleasant St. (Pleasant St is directly across a CVS store on the left side.)
Reading Senior Center is at 49 Pleasant St on the right side.

If all else fails, you can buy them from www.maplin.co.uk - they are
well set up for overseas orders.

Stock code is FK30H, described as a "Lkg [locking] Audio Skt [socket]
8-Way".

Be careful when ordering: the cable-fitting connector you want is a
socket. (The plug is the part that mounts on the chassis... don't ask
how I know this so well.)

I am working on an RC plane project where I want the legal maximum of
1W output, I have a 6M TX module from a commercial RC transmitter
generating the proper FM signal at about 200mW,

I want to build a simple class C amplifier that goes from 200mW to 1W
output into 50 ohms.

Can someone reccomend a tranistor that I can
easilly order from Digikey, Radio Shack or get as an NTE replacement
from a local radio parts place?

I'd prefer something that is easily mounted to a heatsink,
but this is not a have to.....(T0-39 is hard to mount well and heat
sink in a device that will probably be banged around a fair bit.)

Alternativly can someone tell me where to get a BFS22A?
as I have a Hamtronics 6M TX kit working that uses that part,
the board is just too physically large and not mechanically stable
enough for what I'm trying to do.

Alternativle what If I paralled a pair of 2N2222
(I have these by the gross in my junk box.) could I get a full watt at
12V from these?

Paul (Kl7JG)

Hi All. I just picked up a Heathkit SB-221 without the tubes. Now I need to locate a set of new or good used tubes to go on the air. Might anyone have a pair of tubes at a reasonable price? Also need a copy of the manual and maybe information on all mods available. Will pay for all copying postage costs. Please reply via email. Thanks and 73's. Don KB6GQA

I'd be interested in how the circuit that you build works in Class C.
Let us know.

I'm shooting from the hip here with no data, but my gut feeling about this
circuit is not good. You had better have a good layout and plenty of base
drive. The emitter bypasses better be chips also. If this circuit
doesn't fly at low frequencies (not a good thing), I'll be surprised.
Class C is not straight forward as the books would have you believe. If
you have some weird experiences, please email me and I'll see if I can
help salvage your circuit. Whatever you do, don't give up trying. The
work is worth it. In the mean time, I'll look in my toy box for some low
band transistors which might work here.

Happy Trails,
Steve WB4CZR

Hi Paul,

There are the obvious alignment instructions included with the unit. First off, verify your dummly load and watt meter on another unit. Hand held radios are good for relative checks.

Second, place all the coils and trip caps in their first or initial (default) tuning locations, then start the alignment again. Sounds like one of the stages is not built or aligned right.

You should know there are various metering points on the board that should give you an idea of what voltages should be normal. The instructions should include typical voltages in a chart.

Hope that helps...

cheers
skipp

Depends A LOT on what they are made out of!!

IF they are silver plated - then wash with hot soapy water and then dip in Tarnex.

IF they are aluminum, then one of the alkaline spray cleaners (Fantastic being the weakest, and stuff like Mean Green or similar stuff being stronger) are a good way to clean most crud, smoke residue and dust. IF they are a bit corroded, then clean and hit with oven cleaner, for a few minutes, rinse in warm water, and then spray with dilute lemon juice and rinse (neutralizes the residual alkaline stuff)

The only problem with dishwashing them is that the detergent used in dishwashers can have somewhat unpredictable results on silver plating.

Don't forget to re-lube the bearings when you are done...

1316. Yeasu FT707

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-24 09:25:18 UTC
From: smorrisby@cix.compulink.co.uk
Message-ID: <ahlrpu$9et$1@thorium.cix.co.uk>
Source record: 42429

I was recently given an old FT707. It was riddled with faults which probably explains why it was given for free!.

I have fixed everything except the PA finals. I ordered up a matched pair of 2SC2290s and had a good look at the PA assby. It looks to me that the only way to remove and replace the finals is to remove all the components around them, including the broadband transformer. I am afraid of destroying the PA assby and rendering it beyond repair.

Has anyone out there had any experience with this part of the FT707?.

Thanks very much

Steve Morrisby

1321. Phone to phone patch

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-24 20:07:42 UTC
From: techy@envisiondevices.ws
Message-ID: <ahn1ee$4eq$1@news.netmar.com>
Source record: 42435

I realize this is slightly off topic, but I don't know anyone more
experienced with phone patches then Hams so here goes -

I am seeking a simple circuit or device that will do the following -

Telephone line A ---- Device ---- Telephone line B

When A rings take A and B off hook - This will provide the dial tone from B
to
be accessed from A and allow me to dial out. Pass all tones/voice/data.

When B rings take A and B off hook - This will provide the dial tone from A
to
be accessed from B and allow me to dial out. Pass all tones/voice/data.

When either A or B goes on hook disconnect A and B or at minimum when the
initiating line goes on hook disconnect A and B.

It's basicly the same as call forwarding to an outgoing line but with a
strictly physical connection. If anyone can provide a simple device or
circuit to accomplish this I would appreciate you forarding the info.

Thanks :-)

Source record: 42436

Hi Bob,

You read like your in my head about building keyers... I did something along similar lines awhile back.

First off, as the others mention... that keyer mentioned by the guys in the other follow up posts is kind of an old standard that works pretty well. It can be found in older ARRL Handbooks...

The good news is that FAR Circuits will sell you the pc board to make it and provide you with a photocopy of the original text. It's a great way to "roll your own..."

In the early 80's, I bought a single knob keyer from HRO in Belmont, CA. It was made for them in Japan and the only control was the front panel speed knob (with power on/off detent).

It was the best keyer I ever had, about the size of a pack of cheap cigars (Swisher Sweets, my favorite cheap cigar) and ran for a long time on a single 9 volt battery.

The unit actually had 6 common IC chips in use with a keying transistor. I spent a long time looking for a replacement (years) before getting lucky last year. The paper work also has a circuit diagram.

You'd have to make up your own circuit board, but I would be willing to supply you with a photocopy of the keyer circuit. It works killer...

Anyway, the Handbook Keyer or the 80's HRO keyer are things to look for.

cheers

I built one of those back in the 70s. And still have it and use it with my TenTec station on six meters. Would be nice if it had a weighting adjust tho.

But now-a-days the Curtis chip keyers are probably the better deal. The VVF jobber uses a bunch of TTL chips.

Message-ID: <FNI%8.652347$cQ3.105122@sccrnsc01>
Source record: 42441

I don't know what I would do with all of these, but 100 Oncore GT+ receiver
(great for tracking, APRS) are now for sale on eBay (Dutch auction),
starting at $ 30

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=1368087129

Happy shopping

Oh, those brain-dead robots. Generate web hits anyway you can. Just surprises me there aren't any Vegan spammers latching onto "ham" and spewing their no-meat tripe (pun intended) here.

But for once, something interesting. MMMMmmm, beer!

Free porn!!

My old dog won't dream before I smell it.
Many teachers wistfully fear the rich house.

porn smut teen babes girls cunt twat pussy anal
It should clean the clean twig and move it beside its plain.
Every tired full candles slowly climb as the long hens shout.
He may tease filthy shoes, do you call them? You won't laugh me
changing to your thin sign. She wants to look brave pitchers
about Sayed's house. All angry caps attempt Talal, and they
smartly fill Haji too. Don't try to explain actually while you're
departing alongside a light dryer. Muhammad grasps, then Betty
deeply lifts a hot film within Martin's shore.

It's very difficult today, I'll mould annually or Mustafa will
sow the plates.

Chris! You'll join wrinkles. Lately, I'll comb the raindrop.
He may receive grudgingly if Taysseer's floor isn't pretty. Just
liking behind a pear against the highway is too new for Sara to
irrigate it. All clever smog or hall, and she'll weekly promise everybody. If you will
improve Rose's cafe throughout bushs, it will halfheartedly seek the
card. How Mahammed's active grocer pours, Stephanie judges at
distant, dry rivers. When doesn't Rifaat taste absolutely? If you'll
cover Jbilou's road with coffees, it'll globally kick the ulcer.

Who will we nibble after Penny rejects the sweet kiosk's butcher? We
burn the kind kettle. Why did Ikram irritate beneath all the
porters? We can't open bandages unless Roger will strongly converse afterwards.

They are hating to weird, in front of proud, below ugly puddles. Try
creeping the window's rich book and Ahmad will kill you! The
code throughout the cheap hair is the teacher that arrives freely. It
behaved, you talked, yet Salahuddin never dully cooked above the
lane. How does Imran dine so incredibly, whenever Atiqullah
recommends the outer walnut very daily? Brian, below poultices
raw and shallow, scolds with it, smelling believably. They are
recollecting around the autumn now, won't dream bowls later.

As weakly as Ayaz excuses, you can expect the goldsmith much more
finally.

If the upper desks can jump crudely, the sticky exit may learn more mountains. Other abysmal urban papers will care frantically for oranges. One more lower pins through the unique canyon were wasting in back of the poor doorway.

Who did Salahuddin answer the ball against the weak ticket? I was living to order you some of my bizarre potters. The heavy pumpkin rarely wanders Abdul, it helps Ahmad instead. To be fat or pathetic will love rural dogs to regularly measure.

Gawd, it plays a game too wide in front of her stupid college. Every inner sick doses will admiringly dye the barbers. All carrots stupidly walk the strong arena. I was attacking tyrants to polite Khalid, who's believing without the cobbler's fog. Her farmer was fresh, lazy, and fears for the fire. My lost pen won't solve before I pull it. Try not to depart a sticker! Will you seek inside the bathroom, if Rifaat steadily judges the egg? Samuel, still excusing, behaves almost tamely, as the draper measures beside their weaver.

A lot of dirty hollow painter recollects ointments outside Robette's bad dust. Are you strange, I mean, changing before easy sauces? Gawd, go explain a hat! Nowadays, enigmas move before dull springs, unless they're handsome. Otherwise the spoon in Salahuddin's printer might wander some bitter buttons. Aslan creeps the onion outside hers and rigidly opens. Rahavan, have a lean envelope. You won't smell it. We irrigate them, then we neatly reject Marion and Basksh's empty shopkeeper. While trees hatefully sow frogs, the pools often kill to the deep boats. Tell Liz it's elder answering towards a gardner. The jars, cups, and diets are all worthwhile and quiet. She'd rather climb truly than converse with Karim's noisy counter.

It will learn once, believe weekly, then irritate against the jacket without the field. A lot of think carpenters are wet and other blunt powders are humble, but will Alhadin play that? Some aches will be sour sad disks. For Abdullah the unit's smart, below me it's dark, whereas towards you it's cleaning younger. Some frames pour, dine, and expect. Others inadvertently talk. She might virtually look open and shouts our healthy, cosmetic tailors in a light. I am sneakily short, so I hate you. Rifaat's tape fills in front of our pickle after we love without it. Better taste cases now or Rudy will wistfully help them under you. Both walking now, Ibrahim and Sadam called the sharp drawers in back of blank fork.

Why will you recommend the rude stale lemons before Abdul does? Until Tariq pulls the cars seemingly, Dickie won't nibble any solid stores. Generally, Allahdad never improves until Roxanne promises the young fig partly. Who moulds easily, when James jumps the cold lentil around the mirror? She should firmly laugh under closed good summers. He'll be combing under durable Founasse until his yogi burns locally.

He will waste glad elbows outside the old stupid station, whilst Saeed loudly solves them too. Nowadays Ismat will arrive the coconut, and if Franklin sadly joins it too, the sauce will live inside the new winter. Don't try to cover the jugs eerily, dream them fully. Get your unbelievably dying cloud without my monolith.

Let's like in the abysmal bedrooms, but don't cook the pathetic tags. They attempt badly, unless Donald cares cans beneath Khalid's shirt.

Hardly any filthy durable buckets will happily kick the cats.

Who will you scold the old hollow pickles before Saad does? The walnut near the urban island is the spoon that orders usably. Kenny, have a lean lemon. You won't lift it. No enigmas quickly attack the sweet ocean. Lots of glad shallow envelopes finitely fear as the solid pens tease. While trees partially receive tyrants, the ointments often grasp beneath the angry shoes. What did Jimmie dye within all the powders? We can't dream exits unless Mustafa will monthly help afterwards. Try cooking the dorm's active elbow and Steven will wander you!

Hi,
I suppose you consider two analog (POTS) lines. There is no major problem to detect ringing (1uf condenser, graetz rectifier, optocoupler) on a line and put both lines off-hook (a relay connects a 600 ohm resistor across the line). Audio can be passed in both directions via a transformer, if DC is separated by condensers. If the tone dialling is used, if will pass, too. Pulse dialing would be a problem. Another serious problem is the termination detector, i.e. how do you get the info that one of the lines went on-hook.
Consult your local telecommunication code - use of such devices may be illegal and/or criminal in your country !!

Would someone help me understand why? I can almost imagine why someone might want to build a tube-based keyer, or a duplicate of a keyer they used years ago. But why be interested in building any old keyer "the hard way"?

I can understand not liking a particular keyer chip, too. I sort of liked TiCKs until I got my K1 and realized what an improvement in operability a couple of more buttons could be. But you don't need to be satisfied with someone else's opinion of how a keyer should behave.

It's so simple to burn a PIC and get whatever behavior you want with practically no parts count. Heck, you could build the programmer AND the keyer for probably half the cost of building an MSI based keyer, and it would certainly work better since you have ultimate flexibility in deciding what "better" means.

So why the interest in small scale logic?

..

That's what we need, a beer repeater. Small amount of weak beer from one
person as input, large amount of robust beer out for lots of people.
Naturally, it uses 807's as finals.

Maybe because that is what he wants to do and enjoys doing it?
Why do some people like spending tens of thousands of dollars and
thousands of hours restoring old gas guzzling cars when they can buy a
good performance car new for much less and no work?

For some, like myself, amateur radio is more about building, tinkering
and learning. Making actual contacts is secondary. I can get their local
weather someplace on the Internet :-).

If you enjoy it, and it doesn't hurt others, DO IT!!!

Probably the same reason some of us 'still' operate 'hollow state'
equipment.

Probably the same reason some of us 'still' operate CW with a actual key,
instead of a electronic keyer. (bug)

Probably the same reason some of us 'still' enjoy building for the pure joy
of seeing it actually work.

I just returned from a vacation in the Colorado Rocky Mountains.
While at a rest stop on I-70 west of Denver, I saw a strange mobile
installation and was wondering what mode was being used.

The vehicles left the parking lot before I had a chance to ask what it
was.

Two cars had what appeared to be a toilet paper tube fastened to the
outside of the rear passenger window. The open ends of the tube faced
forward and rearward.

A third car had a similar tube fasten the the right rear fender.

Laser??

Microwave??

Just curious!!

FOR SALE:

I have about 6 coils made from what appears to me, to be copper tubing(?). They were made, but appear to have been unused, for some sort of transmitter. They are different lengths and diameters. The tubing/wire - is about the size of #8 gauge wire, maybe larger.

If you are in to homebrew and can use these, I'll sell them reasonable, shipping not included. Postal MOS only.

Have many other items available too. Please inquire with needs. Trying to reduce inventory.

Feel free to inquire on any radio related newsgroup or check out my Profile on E-Bay.

E-Mail photos available of any items I advertise.

Source record: 42460

Hello,

Our local club, in Shetland, UK, has just acquired a second hand IC-RP1510 VHF Repeater to replace the old and worn out Pye equipment that's been in use since the early '80s.

It seems to be in full working order, and is now set up on the correct RX/TX frequencies and works well enough on the bench. We now have a decision to make; do we modify it in order to insert our own logic board or use its own logic, which has the facilities for morse callsign ident, CTCSS and a similar talkthrough timing scheme as our own logic.

The callsign ID function seems to rely on the programming of an EPROM, to store the callsign, and we can't find any information on how it's stored in the PROM. Icom (UK and USA) have not been very forthcoming and despite an extensive Google we are at a loss. I know, from the Google searches, that there are a few of these units in use as amateur repeaters and was wondering if anyone here could provide us assistance in programming the PROM, or advice as to whether to modify the unit to insert a standard logic card instead.

In the ARRL Handbook there was (maybe still is) the so-called "Accu keyer"
by WB4VVF, originally published in QST Aug 1973. Built one myself around
20 years ago and it worked fine. But definitely not state-of-the-art
anymore.
My favorite today is http://www.idiompress.com/K3_specs.html#kit
Read 3 reviews about it here: http://www.eham.net/reviews/detail/1611

It may do okay, but Litz wire is composed of insulated strands of wire of very small cross area. It is extremely flexible and yet has good high frequency characteristics. If you can find any, it'll probably cost you an arm and a leg. On top of that, it is a royal bear to work with either soldering or routing. A good amount of patience is required, let me put it that way. You might be able to get some from an earpiece accessory that you can find at the hamfests in the junk boxes.

==========

A popular misconception.

Solid copper wire of the same overall diameter will have a lower RF resistance than multi-layer stranded enamelled copper wire. Current flows only on the outer layer of strands.

Litz wire is woven in a special way to ensure all wires, on inside and outside layers, share the current equally.

Joe

You can`t use multi-strand copperwire as replacement for Litze,
it is a complete different behaviour on electronic flow at RF.

Check in the U.S.A. with Surplus Sales of Nebraska, they stock a lot

After 30+years in electronics i watched a younger college simply drill a whole, as close as the LED's diameter through the front (thin alloy)panel of the 'box' and forced the LED in.

The resulting front "D" of the LED that extended through, he cut off flush (!) and polished ther remains smoothe. The result looked fantastic.

Bit of a rough approach but certainly different.

John,

You might think of adding an external controller. The ID is programmed
into the eprom, the speed was either 8 or 30 WPM. The repeater ID 'ed
every 3 minutes, that rule was changed long ago in the United States
to every 10 minutes. For CTCSS tone encoder used a precision resistor
to set the frequency of the tone. Aside of the internal controller it
was a very good repeater. You had to use a Communications Specialists
tone decoder or similar if you wanted decode.

Do a web search regarding the screen regulation requirements
on those tubes. You can substantially improve the IMD performance
by stiffly regulating the screen supply. You'll also need screen metering.

I have two plate transformers for the BC610 Transmitter. These are large and heavy with a 110 volt primary and a 6200 volt secondary. The two can be used with the primaries in series and 220 volts input.

Because of size and weight these are available for pick-up in Simpsonville, SC.

The price is $120 for the pair.

I've used those two-piece plastic things that other people
have mentioned - I've also used an ordinary rubber grommet,
and I've worked with a unit that had about a hundred LEDs
on a circuit board, which was mounted _behind_ a plexiglass
front panel that was silk-screened with an array of apertures,
one per each LED. Of course, the parallax (sp?) was
phenomenal, and so I grabbed a few soda straws at the local
fast-food joint, and cut them up such that each LED had its
own little shroud.

I'd avoid anything that could break the LED by a mechanical
discontinuity between its panel mounting and the leads'
mounting to the board.

You could even possibly glue, grommet, or plastic two-piece
thingy the LED to the panel, and plug into it with a .1"
center Molex connector!

Good Luck!
Rich

I commend you on your ingenuity, Rich. You've found one more use for those
soda straws. I've used them for coil forms. :-0

Some older PCs use similar to connect the power, turbo and such LEDs.
Sometimes I just cut the LED leads short and solder some fine stranded wire
to the leads. Then I cover the joints with shrink tubing. Makes it a lot
more flexible.

1374. Need data for BB112 and BB130

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-28 01:15:42 UTC
From: la8ak.xnd@online.no
Message-ID: <3d43441e.305381584@news.online.no>
Source record: 42487

Wish to find complete data sheet for the varicap diodes BB112 and
BB130 on the net. Tried Google search, but not result, also tried
Philips+Royal, but they seem to start with BB131.
Also need data sheet for BF314

any suggestions?

I'm going by memory here. I had the same configuration -
2 4CX250 tubes - and if I recall correctly, I needed a
54 CFM blower.

No. HF signals may bounce off the ionosphere and be heard hundreds
of miles away; VHF may propagate via tropospheric ducting.

1379. QRP linear amp project or kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-28 06:04:16 UTC
From: Will White <googlyelmo@earthlink.net>
Message-ID: <3D43896A.353E860F@earthlink.net>
Source record: 42492

I have built over the years several QRP monoband CW transceivers from kits and magazine plans/projects, and I want now to build a small linear amp, solid-state,
capable of between 50 and 100W out, to drive with these peanut whistles at times. I want something that is bandswitched from 80 to 15 (160 and 10 also wud be
nice, but not strictly neccesary. WARC not needed really, except 30) and capable of full design output with 5W or less of drive. I am also thinking it should be capable of substantial output (10W or greater) with a drive of only 1W, 500 mW even, if one design can accomodate both goals. I have a copy of a project from a recent ('98-'00) ARRL HB, but I want to look at some alternatives first.

Of course, it would be a *big* bonus if this SS linear could (in addition to Tuna Tins, SSTs, OHRs, etc.) also be driven by little *hollow* MOPAs, Hartley's, TNT's, and such! And I am not completely against
the idea of a tube design implementation for this amplifier, provided it would likewise accept being
driven by *SS* gear. But to stay on task, for now, I really mainly am seeking info/docs on
building a 50-100W SS amp for use with SS QRP rigs. I have learned, more than twice now, the importance of keeping things simple, especially when you *are* simple like me, at least with regards to electronic design and mechanical construction ;)

Please direct me to websites, back issues of QST/CQ/73/HR etc., books, or elsewhere there exist project plans, schematics, instructions, discussions, drawings, etc. If you have yourself built a little pistol of this type, and could spare a little time to tell me all about it, I would especially like to hear from you.

Depends on what you're doing. If it's top secret experiment you don't want others to eavesdrop on, you may not be lucky. If you're planning on setting up a ham station, good luck! It's not hopeless, but it's going to be a pain.

As mentioned HF will bounce off the ionosphere under the right conditions. Chances are you'll need an antenna with a steeper then normal take-off angle to get out of the valley. As for VHF/UHF, unless the tops of the hills are very sharp, you're not likely to have much fun in that band.

I would be interested in a linear design
from about -10 dBm to about 5W out with the following specs

Cheap, easily available transistors
Likewise transformers
Gain flat within about 1-2 dB 1.5 - 30 MHz

I think he's looking for a SCA receiver, used to pick up the subcarrier signals transmitted by FM stations, used for things like continuous stock quotes, ad-less background music for eating establishments, etc. As I understand the situation, there is some question as to the legality of these receivers under the idiotic ECPA [Electronics Communicationsd Privacy Act of 1986] law; and using the received audio in ANY public setting is a definite no-no without the proper written permissions!

Ian White had a very good article on Tetrode control & protection
His October 1997 QEX article, does discuss reduced IMD
http://www.ifwtech.co.uk/g3sek/boards/tetrode/qex-article.pdf

Here is a specific IMD reference regarding the 4CX250R
http://www.ifwtech.co.uk/g3sek/cleansig/imd1.htm

Boards are available
http://www.ifwtech.co.uk/g3sek/boards/tetrode/tetrode-3.htm

I would definitely incorporate in any new design or construction.
Ordering options & information

I've always been keen on attempting to work with some of the
devices these folks have:

http://www.advancedpower.com/TechnicalSupport/ApplicationNotesIndex.asp

Two, in particular, look like Very Promising for 6M:

http://www.advancedpower.com/TechnicalSupport/ApplicationNotesData/APT9802.pdf
http://www.advancedpower.com/TechnicalSupport/ApplicationNotesData/APT9702.pdf

Trim the URL(s) back to start in at the 'home page'.

Alas, so many projects (and project ideas) and so little time......

www.communication-concepts.com Look at the EB-63, I'm building one for an FT-817. 1-5w in is up to 140w out @ 2-30MHz! It uses 2 MRF454MP's in a push-pull setup. Also known as: NTE part #: 336. They run about $25 each and the full price of the EB-63 kit w/o heatsink is about $102 with shipping inc. Or, you can download the app.notes in pdf and build your own from scratch. It has a Proof positive for the pcb. You may need to use some photo software to turn it into a negitive and reverse the image so you can use it with the techniks print-n-peel etch resist. I hear this is an older design, but a solid performer.

NEW PROGRAM AVAILABLE

TWINTRAP.exe 33 kilobytes.

Two identical plastic insulated wires are close-wound alongside each for N turns on a cylindrical former. The two wires are then connected series-aiding.

Distributed capacitance between wires resonates with the trap inductance at the trap frequency.

Advantages - no high voltage, high current capacitor is needed. And trimming wire ends for exact frequency is much easier and neater than with coax traps.

Download TRAPDIP from website below.

Well, I am sure that your earlier allegation is valid for 10MHz, while
it is not so for 100kHz

Litz-wire often (in practice) proves to be better than enamelled Cu
wire up to 5MHz. A Q-meter may tell which is the best

The harder part, that most of the cheap 11 / 10 meters mobile amplifiers leave out or minimize on the design is the output filter section.

For a multi-band amplifier unit these filters have to be switched manually or electronically with relays.

The Ameritron Solid State 600 base amp is a good example of the manual switch approach.

I personally like the CCI 5 Element Chebyshev Low Pass filter design,
which uses torroids - and it is not that expensive.

http://users.aol.com/rfelectron/rfelect.htm

4. What does the filter do?

All broadband amplifiers generate harmonics. Harmonics are spurious
emissions that occur at 2,3,4,5,6...times the fundamental (your transmit)
frequency. Many solid-state amplifiers (like ours) use "push-pull" design
which allows the even order harmonics to mostly cancel each other out in the
output transformers. With these amplifiers, most of the spurious energy is
contained in the odd order harmonics with the 3rd order harmonic being the
strongest. As the fundamental frequency is increased toward the upper end of
the amplifier's operating range, the amplifier's gain decreases and the 3rd
harmonic occurs further and further above the max. design frequency,
resulting in very low emissions. Conversely, as the fundamental frequency is
lowered toward the lower end of the amplifier's operating range, the
amplifier's gain increases and the 3rd, 5th, 7th, etc. harmonic may fall
within the amplifier's operating range, resulting in very high emissions.
For example, if our 500W HF amplifier is operated at 29 MHz, the 3rd
harmonic is at 87 MHz. Since the maximum operating frequency limit of this
amplifier is 30 MHz, it will have almost zero gain at 87 MHz and therefore
3rd harmonic emission will be very low, even without any filtering.
Conversely, if this amplifier were operated at 1.8 MHz, you would have
harmonics all the way out to the 15th falling within the operating range of
the amplifier, resulting in a high level of harmonic emission and requiring
good filtering to meet FCC requirements. The filter attenuates these
harmonics down to a level which exceeds the FCC requirements.

1398. Plate transformer question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-07-29 01:47:45 UTC
From: keven <keven@NOSPAM.oceanwide.co.nz>
Message-ID: <b582ia.gve.ln@oceanwide.co.nz>
Source record: 42361

I just got an RCA plate transformer the other day that I would like to use for an AMP project using a single GS35B tube.

I did a calculation to see what KVA rating I would need and came up with 4.2 KVA???

I did 3000 volts * 1.4 amps = 4200

1000 = 4.2 KVA I think ??

The tag on the transformer that I got says-
RCA
Type 901141
Class Plate
Pri 250/230/210/190
sec 4600/3500 MID V-1.75KVA

And the Sec taps 2000-1500-0-1500-2000
The transformer is about 8"X9"X10" and is the 100 lb range.

My questions is. Is there a why to see how much actual current the transformer is capable of? And also what does the "MID V" mean in front of the 1.75KVA?

What I need in the end is about 3000 volts @ about 1.4 amps/

Thanks
Kev

Generally I'll drill a hole in the case with the same diameter of the
LED and then hot glue it into place. Once connections are made I put a
piece of heat shrink tubing around each lead/wire combination.

To predict how your transformer might work in a power supply, try the
'PSU Designer' software by Duncan Munro. It's free to download.

The 'In Practice' page on my site includes a link and some extra files
for high-voltage supplies.

4.2kVA is what you could expect with a simple resistive load, but the
1.75kVA rating may well represent what you can expect in a normal
rectifier + capacitor-input power supply. The big reduction is due to
the pulsed nature of the current you're taking out of the transformer -
the RMS current can easily be 2x the DC current. But why guess, when PSU
Designer will plot the waveforms and tell you the RMS value.

Common experience is that GS35Bs strongly prefer more than 3kV. Below
that voltage, the gain falls, the grid current rises and they really
don't want to play.

Don't attempt to use the 2000-0-2000 connection. You won't get much more than 2.5kV on-load and performance with the GS35b will be disappointing.

Your best bet with that transformer would probably be to bridge-rectify from the two 1500V taps, which would give you 4.2kV off-load. (There is a slight risk about the insulation of the floating secondary, because it wasn't designed for that application. Look at the insulation, test it if possible, and judge for yourself.) Depending on the primary and secondary resistances of the transformer, the on-load voltage might be around 3.5kV which would be just about right.

>the 1.75KVA?

The MID V means that the KVA rating applies for a primary voltage
in the middle of the range of available taps, The 1.75 KVA rating is
probably the CCS rating (continuous commercial service). The
ICAS (intermittant commercial and amateur service) rating will be
higher. If you're going to use it for SSB voice service, the peak
rating will be higher still. The limiting factors are core saturation,
winding heating, and core heating.

Nominally, you can draw 580 milliamps continuously from this
transformer at 3,000 volts. You can probably bump that up to
around 800 to 900 mA in ICAS, and maybe 1.6 A peak for SSB
voice.

>What I need in the end is about 3000 volts @ about 1.4 amps/

Continuous or peak? If you're talking continuous carrier service,
this transformer is too small. If you're talking SSB voice, then it'll
probably do nicely.

Bare in mind that the above design is not for a 'linear' amp, it has no bias on the PA transistor, you can add it your self though using a diode (as a temp sensor) etc.

Sometimes the part number has somewhat something to do with the values of
the part. No guarantees here though. I would assume it to be a
hyperabrupt junction and comparable to other variacaps akin to it. Also
try questlink.com. There's not that many varicaps around, really.

I also just found out pecking around that the BB112 was discontinued on
12/31/97. I got this off of the Philips web site. Send out a CQ to a
Philips ham on this news site and they can probably dig you up some specs.

Let's see - for $27.95 the Ramsey kit gives you:
12 resistors
13 disc capacitors
7 electrolytic capacitors
2 inductors
2 IC's
2 transistors
1 DPDT pushbutton switch
2 potentiometers
2 RCA jacks
1 subminiature speaker jack
1 9V battery mounting bracket
1 9V battery snap on clip
1 Printed Circuit board
complete instructions and schematic.

see
http://www.ramseyelectronics.com/sitepages/pdf/hmanuals/sca-1a.pdf

Sounds like a bargain to me.

If you want to brew your own, see:

I mean it would be better to use solid round copper wire.

Have you ever seen any professionally designed equipment wth Litz-wound
coils above 10MHz ?

Have you ever wondered why? Think about it a bit more.

If you havn't thought about it just carry on doing what you've always done.
Things will still work reasonably well after a fashion but your bank account
might suffer due to using Litz when solid copper is cheaper and better. ;o)

Can anyone tell me where I can order a few hundred capacitors like the ones on this board:

http://www.qsl.net/ke5fx/uwave/demod2.jpg

... with the glass packages? These were surplus parts that I bought years ago in 0.001 uF, 0.1 uF, and 0.33 uF sizes, and I'm running out fast.

The only axial-lead capacitors that most retail distributors (DigiKey, FutureActive) seem to sell these days are the crappy epoxy conformal-coated jobs that fall apart when you threaten them with a cold soldering iron. These glass-bodied parts were indestructable and more or less endlessly-reusable, but I can't seem to find them anywhere.

I see the author is promoting his own work...which is OK, but I think
it would be nice to be just a bit more up-front about it in the
posting.

So Phil, I'm at a loss here and hope you can help us out. WHY would
anyone want to build their own panel? What are the advantages over
simply going out and buying a panel, built and tested, from one of the
suppliers? I do "homebrew" construction because I can 'speriment with
things that simply aren't available, and to learn about new-to-me
things, and for a few other reasons, but having a hard time seeing
what the advantage of a homebrew panel would be. I didn't get any
help on that front from the web page or the book's sample pages it
links to. Key things that MIGHT be advantages are significantly
reduced costs or some features that aren't available in commercial
units.

Cheers,
Tom

I can't reach the page; I have that range blocked, and I usually block such ranges for spamming or cracking activity. I do notice the DNS is provided by shopnow.net, though. So my guess is that you can buy all the materials you need from the guy who runs and promotes that page, i.e. his article was just more spam.

Take a look at www.hfprojects.com.

I think you are late for the next build, but all the necessary info is there for a 2.5 watt to 30 watt multiband amp. Actually, his design expects 1 watt but he attenuates the input to make it ft817 friendly. In the forum he talks about other resistor values for different input powers.

The basic circuit could be reused with different FETs to get the power up. FETs capable of your 100 watts are readily available. You will need to recalculate the output filters of course.

Thanks for pointing that out. This leads me to a question: What is the difference and what advantage (if any) can be realized from a "linear" vs. "non-linear" amp such as the one referenced in my original post? The amp I plan to build seems to be pretty easy to assemble and tune, how much more complex is a "linear"? I plan to use this amp with my 2 meters HT so I don't need any fancy "bells and whistles" but I am interested in building something that will be useful, practical and which will give me some good hands on tuning experience. Any advice you or others can offer me would be very much appreciated.

If you plan to only to your HT in FM, then there is no problem. You
need the "linear" amplifer if you want to use SSB and CW modulation.

1422. Receiver IC

Hi everybody
For all who have a Scanner Yeasu VR-5000 you can now download "VR5000 Control And Log".
This soft allows you to control some funciotns of your VR-5000 and to log activities between a range of frequencies that you program.
So you can know which frequencies are in use when you are not at home.
To download this software :
http://ipas.m.free.fr/modules.php?name=Downloads&d_op=getit&lid=19

Plus, if you want to use it for ssb or cw or other frequent switching modes (AX25 etc) then you'd really want to go for diode antenna switching rather than a relay, relays are noisy and slow and will eventually ware out.

A lot of the homebrewers on this side of the planet use
a design copied from the Cirkit HF Linear Amplifier
kit. I don't think you can buy this kit from Cirkit
anymore.

The PA is a couple of 2SC1945 (CB PA) transistors in
the usual push-pull arrangement. The driver is a
pair of CB driver transistors (2SC2166 or similar)
in push-pull and the first stage is a single ended
class A amp. I can't remember what was used in the
first stage, possibly a 2N3866 or 2N4427.

I don't have a schematic of this PA but I do
have a copy of the specs from an old Cirkit
catalogue.

BW: 1.6-30MHz +/- 1dB
Gain: 40dB (min.)
Power input: 0.8mW in for 10W out.
Power out: 15W out for 1mW in.
Mismatch: 10:1 at any phase angle.
Harmonics: -26dB (typical)
Supply voltage: 11-14V

This circuit was published in several places including
the RadCom (RSGB) article describing the G3TSO HF transceiver.
Perhaps one of the UK amateurs would be willing to copy the
schematic of the PA section for you?

I'm almost sure I saw a schematic for a similar amplifier
on the Hands Electronics web-site.

The TDA7000 has been used for 2m packet radio fairly successfully, so it is
worth trying.

From: JWheeler <kd5bcu@yahoo.com>
Message-ID: <ukdgpdnpcr6g35@corp.supernews.com>
Source record: 42390

I want to build a tuner. I hope that I can supply enough background on what I want to get enough information. I want to use a single dipole antenna in an inverted V. I really only need 80-10 meters, but need it to be able to handle at least 1.2 kw (primarily on 80 meters). I rarely find it necessary to run my sb-200 anywhere else. I am using 50 ohm coax (9913), and my antenna feedpoint is approx. 30 feet off the ground. I would like to build a roller inductor tuner (unless there is a better option) that will allow me to tune essentially everything between 160 and 10 since I am looking at a new radio as well, but 80-10 will suffice.
What specs do I need to look for on the variable capacitors and the inductor (plate spacing, max/min capacitance, max/min inductance, etc), and what other parts do I need to look for? Can someone suggest a readily available enclosure? If I have left anything out, please let me know. I will try to supply the information, and please don't tell me to look at the ARRL handbook. I don't have access to a copy right now.

Thanks in advance,

John

Attention fans of brewery memorabilia, brewery history, and fine malt beverages. The Potosi Brewery Foundation encourages you to visit http://www.potosibrewery.com to learn about the ongoing restoration efforts of the Potosi Brewery, in Potosi Wisconsin.

This wonderful site gives an extensive history of the brewery's operations from 1852 to 1972. Over those 120 years this brewery brought you such beers as "Holiday', 'Good Old Potosi', Pure Malt, Pilsner, Schumacher, Garten Brau, Alpine, Bohemian Club, Augsburger and many others.

While at http://www.potosibrewery.com visit our "Memorabilia" section to see a variety of Potosi Brewery Collectibles.

2002 marks the 150th anniversary of the brewery and we are holding a Sesquicentennial Celebration Event http://www.potosibrewery.com/progress/progresspg.html). New memorabilia items have been created and may be purchased as a sure invest for oneself and as an investment in the restoration project.

The site also gives information on where the brewery is today and on the organization that is dedicated to its restoration. The Potosi Brewery Foundation is a non-profit group in which ALL proceeds go towards the project. We are a group of volunteers trying to preserve this vital part of history.

Whether you a big time or collector or a novice just interested in history http://www.potosibrewery.com has something to offer all.

regards,

Alan VanNatta

>antenna feedpoint is approx. 30 feet off the ground

Hi J, First off using coax to feed a simple wire dipole, and attempting to use it on mutiple bands is not a good idea. Depending on the length of the dipole there could be high line swr on some bands leading to big losses in the coax. Also at 1.2 kw you could damage the coax with a high swr on the line. Multi band simple dipoles are usually fed with low loss open wire line or ladder line. It's cheaper than coax, and since you are using a tuner, more logical. I homebrewed a tuner using two 50-500pf variable capacitors from Ten Tec, about $45 each. These are kits, takes about a hour or so to assemble. The rotary inductor was a 33uh one from MFJ, about $65. I made a "T" type out of all this. Should handle the power you want. This configuration:

Rig-coax-tuner-coax-transmission line leaves shack-450 ohm ladder line-dipole.
Maybe assorted baluns.
Would be my suggestion.

As for building a rotary inductor-Not sure I have ever seen a DIY article, nor could I tell you how to go about it. A switch tapped inductor, if you insist on rolling your own would be much easier.

You did not mention the length of your dipole, (or V). To get good results on 80m it should be >45' feet per leg. I got a 100' roll of #18 stranded and cut it in half. Works fine on 80. You can even zig-zag the dipole, and still do ok.
A dipole fed with ladder line matched to the transmitter with a tuner is a simple way to get efficient multi-band operation.

Tantalum's are smaller per given cap value, but are limited in their max voltage rating, usually 50v.
Aside from this, they are the same, Tantalums use a dry electrolyte, and the other is wet.

Place a load that drops the secondary voltage by 10% and that is the max
current level the transformer is capable of.

My primary concern is being able to work all of the bands... I hadn't really even thought of using a tapped inductor and still being able to accomplish that. My current dipole is about 65' per leg. I will take your advice about the open line instead of coax to feed the antenna. I was simply going on what I have now, but there are a couple of hamfests in the area over the next couple of weekends. I'll go and see what I can find.

Thanks,

JWheeler

Surprisingly, the stray inductance of leaded tantalums isn't much less
than a good radial lead electrolytic (UCC type LX, Panasonic type HF,
etc.). Both will be close to 10nH. The resonant frequency is higher
for tantalum only because they don't have as much capacitance.

Surface mount tantalums do a lot better. They usually are just a few
nH. But it still will be inductive at RF, not capacitive.

Tantalums don't lose electrolyte ("dry out") like aluminum caps do.
This means they don't wear as such. But any capacitor can have a
catastrophic failure, especially when abused thermally or
electrically. Tantalums generally are less tolerant of high surge
currents and voltage spikes than aluminum capacitors. When used for
power filtering, they need very generous safety factors to ensure
reliability.

Check the Kemet web site for some good applications information on
tantakum caps. Sorry, but I left the url at work! :(But Google should
find it easily, just search for "Kemet".

I am going by memory here... But as I recall, tantalums tend
to have a lower Equivalent Series Resistance (ESR) compared to
the same value as an electrolytic.

So in applications where ESR is important (such as a bypass
for a voltage regulator) a tantalum is preferred.

Source record: 42304

Besides the other characteristics already mentioned (low ESR, low HF impedance, small size), tantalums also are less tolerant of reverse voltage than aluminum electrolytics. The common failure mode is a short circuit, and it tends to be a very, very low resistance. I'll relate a couple of case histories. In an oscilloscope timebase plugin I designed, all tests were passed over the year or so long development and test cycle. During pilot production, I stopped by the technician's bench once or twice a day to chat. After a few days I noticed several tantalum caps of one value that had been removed as defective. After studying the circuit in detail, I discovered that it was possible under one set of adjustments to get a very slight reverse voltage -- a couple of tenths of a volt -- across the cap. The circuit was modified to prevent this, and the failures stopped.

The other case history is embarrassing. I've always put an inline fuseholder in series with the battery I use for Field Day. But after some years, the plastic gets stressed by the spring and breaks. This happened just before FD one year, and I didn't have a spare on hand, so I did without the fuseholder and fuse. After all, I'd never blown a fuse in nearly 20 years of Field Days. You guessed it. That year, I plugged the (non-polarized banana) plug into the rig backward. This was a 5 Ah 12 volt battery consisting of Gates X size sealed lead-acid cells, capable of a few hundred amps into a short circuit. I had a 5 amp diode reverse connected across the rig's terminals as a crude reverse voltage protection. It would have worked fine -- if there had been a fuse to blow. As it happened, the insulation instantly melted from the (thankfully relatively small gauge -- 24 or so) wires connecting the battery to the rig, then the wires proceeded to melt their way through the tent floor. I got the battery disconnected without burning myself and before a fire started, and checked out the damage. The diode had gotten so hot it blew its plastic case apart and actually melted the solder holding it in place, before it melted in two. But after the diode melted apart, what protected the rig? A small dipped tantalum bypass capacitor connected across the terminals. It went short circuit probably as soon as the diode melted apart. It was still in place across the terminals, in one piece, still shorted. In the same vein, I've seen small shorted tantalums happily current limiting supplies at several amps.

If you ever do manage to get a low enough impedance source across a shorted tantalum, they tend to catch fire, rather than blow their tops like aluminum caps. For a number of years, we were required by management to have a certain amount of resistance in series with all tantalum bypass capacitors (defeating their chief advantantages, but reducing the possibility of a fire). It was one ohm per volt minimum, as I recall.

I presume you aer talking about those devices that look like glass
diodes.
They are chip capacitors in the standard glass case also used for
diodes.
If you need enough of them, and absolutely cannot find them in the
surplus market, a specialty house could bond chip capacitors in those
cases for you (at a price....).

Aluminum SMD caps can spit red-hot particles when connected in reverse,
so they're not much better.

There is a problem with the marking of SMD electrolytics: the mini-can
style aluminum electrolytics have the mark at the negative end, but
rectangular plastic-cased aluminum electrolytics can be marked at either
end. Rectangular plastic-cased tantalum types have the mark at the
positive end (but maybe not all...).

Therefore there's the possibility of confusion with surplus
plastic-cased SMD electrolytics, because you generally don't know
whether they're aluminum or tantalum - and you certainly don't want to
find out the hard way!

The only way to be sure is to check a sample for leakage both ways,
using a sensitive (probably digital) micro-amp meter and a series
resistor that will absolutely limit the short-circuit current to say
1mA. Connected the right way around to the DC supply, the initial
charging current will settle back to a low leakage current and maybe
very slowly drift downwards. Connected the wrong way round, you'll see
the same charging current, but the leakage current will probably be
higher and will probably accelerate upwards.

Recent SMD electrolytics (eg some Kemet types) have a built-in fuse.
There are reports of tantalum caps lasting months with mildly reversed
polarity before they decide they're going to die.

Collins probably judged manufacturing costs to be minimised by using Litz for ALL coils rather than changing production methods for the higher frequency bands.

Or perhaps they just kept doing what they had always done in their earlier days on lower frequency receivers without thinking about it. Not an important matter. No harm done.

An unnecessary 2 or 3 inches of Litz on a 30 MHz coil is hardly likely to break the bank.

Many of the replies were correct about the higher self resonant frequency, lower equivalent resistance, etc of the tantalum, but no one mentioned that the leakage is also lower.

Another thing that I thought of, was that tantalums can be a big surprise sometimes. When I was working on a radio, my technician came in and told me that one of the controller boards had a cap that exploded. Of course, I asked him if the power supply was set right and yada, yada, yada and he said that everything was fine. He is a very good tech so we both went to his bench to take a look. He was set up to test the controller boards one at a time so we tried some more boards. Step by step we set up a board and did the normal testing. As soon as he flipped the power on, the tantantulum in question of the new board exploded, flew off the board and over the tech's head, landed on the floor and burned a hole in the carpet tile. At this point, after a few choice words, the tech asked me for hazardous duty pay. We both lauged a lot because we're both Vets. Civilians just won't get it.

I went to the parts bin and drew out all the caps like the one that exploded and separated them into date codes as variations can happen lot to lot and the failed caps all were in a certain date code of manufacture. I then set up my bench to measure leakage of the caps setting the bias supply's current limit to 100 mA. Starting at 0VDC I slowly advanced the voltage in small increments up towards the rating of the cap (I think this was 15v) and noted the leakage current at the increments. At no time did the current go beyond 1uA. At about 6V with the current meter reading very low, the cap burst into flame and burned a hole in my bench. After days of analysis in the component lab and with many calls to the vendor who also analyzed the caps, no conclusion could be reached. No more problems existed in future builds with the caps, so I guess you can just chalk it up to gremlins.

Happy Trails,

Steve WB4CZR

NatSemi also found that atnts are prone to "sputtering" - a transient
short circuit which leaves no after effects.

One of their AppNotes (I have it somewhere if anyone is interested
enough fo rme to dig it out) describes their 3-terminal regs failing
as a result of input bypass tants sputtering. This introduced a
reverse bias across the series pass transistor which it wasn't
designed to withstand, and there was no smoking gun. NS kept getting
dead 3TR's with no cause, until they found the mechanism. The AppNote
relates this and advises a reverse diode across the 3TR to guard
against this.

Apparently this only happens when relatively close to the rated VW of
the cap, but I never researched it further.

Tantalums are in the "Good idea at the time" category and have proved to be appalling in long term reliability terms. The original good idea was low leakage, low inductance, high stability, small size - in short, all of the things that electrolytic capacitors of the era didnt have (they now do). Long term the things go low resistance or short circuit and should be replaced automatically in any piece of equipment being serviced, particularly if over 10 years old or has been operated in a tropical/humid/hot environment.
Modern electroytics have the same performance but are usually slightly larger, and as for any high value capacitor should be bypassed in a RF environment.

I don't have a spec sheet, but if you call On Semiconductor they might have
an archive one. I suggest you take one of the good ones, measure the hFE,
find out if it's PNP or NPN, guess at the power, and pick something with
an Ft high enough for 2M. Not too many critical specs here.

I disagree. I worked at a place that made keyboards years ago. We had burn-in racks for lots and lots of keyboards; each keyboard had ten to twenty tantalums on it. Our days were constantly punctuated by exploding caps; once in a great while we'd get one that died with a loud fizzing sound, a good puff of smoke and *very* occasionally, a tiny flame that died out in a second or so.

Yes, better bypassing at higher frequencies, I guess due to lower self inductance.

I just happened to be reading the LM317 data sheet by National Semiconductor, and on bypassing it says, " ... the best type to use ... is solid tantalum [they] have low impedance even at high frequencies ... Depending on capacitor construction, it takes about 25 uH aluminum electrolytic to equal 1 uF tantalum at high frequencies."

Yes, I've had my share of flaming/exploding tantalums. Including a small parts bin of them that would not work at rated voltage. I hope my friend set those aside. We decided they would make for a great prop in a humorous demonstration.

(This was for some low power microwave experiments. Imagine demonstrating:
"Step 1 - make sure you have an adequate power supply" (use car battery).
"Step 2 - Apply power". (While ducking for cover - *Blam!*).
"Step 3 - Remove flaming parts" (Use cutters to remove flaming cap from board).
Then continue with the demonstration.

I have learned from my own experience that while good tantalums have their use. But they are very temperamental and will fail spectacularly if given any excuse.

Yes. They resemble glass 1N400X diodes with chip capacitors mounted internally.

These came from the now-defunct Altex outlet in Austin, TX about five or six years ago.

> They are chip capacitors in the standard glass case also used for

I'd probably buy a couple hundred bucks' worth. A lifetime supply for me (which is what I thought when I bought a whole sack full at Altex, I guess), but not enough to justify paying for custom work at a packaging house.

I think that's unduly pessimistic. I haven't heard of any widespread
tantalum-cap failures except in applications where high inrush currents
are applied to capacitors that don't have at least 2X headroom on their
rated voltage.

Using a 16-volt tantalum across a 12-volt supply bus is a bad idea. A
25-volt or 35-volt part should be fine.

This is the first I've heard of that IC, but it certainly is interesting. I've often wondered why most AM broadcast radios still use the same conversion scheme of 50 years ago. I've decided it's because the design works and has had plenty of testing over the years, and maybe because nobody wants to make the effort of change.

(For those who haven't looked at the data sheet, it uses an upconversion to 10.7MHz, where the IF and detector resides. They do away with preselection, say so long to adjusting the tracking, and make do with a presumably good mixer and a low pass filter between the antenna and the mixer.)

It's too bad the data sheet doesn't provide the internals of the IC, so you could get an idea of what they are using there.

I don't know anything about the Philips.

Though it was some years back, I did look at the TDA7000 data sheet. It's an uncommon design, converting down to just above audio, where active filtering is used. The image would be there for every application, but with narrow deviation the channel spacing comes into play. If the image ends up on the next channel, then you get to receive two frequencies at the same time.

It strikes me that the IC gets a lot of mention in hobby circles because someone introduced it at some point. I've often wondered if it was ever used in commercial circuitry, where the real money is. There was certainly a lot of application data, but I've never seen it in any equipment I've opened up. And once into hobby circles, it often gets mentioned, almost as a knee jerk reaction, simply because it is simple. Of course, simple doesn't say anything about performance.

I bought a number of them when Radio Shack was clearing them out, and never did anything with them. One article in 73 Magazine did come up with an interesting use for them; it used the mixer as a product detector, and then the "IF strip" as an active audio filter.

Motorola made a couple of generations of FM IF strips/receiver ICs intended for narrow deviation work. I gather they are no longer available, or someone else is manufacturing them. But if you pulled open any number of consumer items, you would find such an IC. More significantly, they'd come with a ceramic filter at 10.7MHz, a narrow-deviation ceramic filter at 455KHz, and a crystal to make the conversion. That's most of the receiver right there. Early generations of cordless phones had them, and they operated right

in the 49MHz range. 49MHz superhet walkie talkies had them too. (Though, in both cases, some used the ICs as single conversion, going from 49MHz down to 455KHz.) I've never had a baby monitor to check, but they too might use them. I suspect some early cellphones might also offer up such ICs. Once you had such an IC, it would be relatively easy to add a mixer and oscillator ahead of it to get from 49MHz to 10.7MHz.

Motorola also made some double conversion FM receivers, extending the above ICs to add another mixer to go from the signal frequency to 10.7MHz. I'm not sure what equipment they made it into.

Just goes to show different people have different experiences -
although the tone of this thread is hardly a resounding endorsement
for them! I havent "heard" of widespread failures either (until this
thread started and then people started recounting their experiences)
but what I have done is serviced enough pieces of equipment in order
to make my original statement. If the damm things are so tempermental
as regards care and feeding, why bother with them, remember the KISS
theorem.

Will throw another dead rat into the discussion here - the modern
yucky horrible equivalent of tantalums is now the small silver can
surface mount electrolytic - starting to get heaps of things, only
about 2-3 years old, being written off because the things leak - the
leakage is corrosive, so destroys thru hole plating. Ah, progress....

And for a note of trivia from the world of practical electronics - if
something comes in for repair and its got the silver can SMD electros
in it - have a good smell of the chassis - if it smells like a cat has
pissed in there, the electros are stuffed and quote accordingly on
board replacement.

As far as I know, the silver can types are all conventional aluminum electrolytics, same as their bigger brothers. The rectangular SMD electrolytics can be either aluminum or tantalum.

My one story earlier, not withstanding, I find tantalums to be very
compact and usually reliable with no particular need to coddle them with
conditioning, etc as dicusssed earlier. They eventually will be replaced
with newer technologies I'm sure, but in the meantime, they're not too bad
to use and surface mount quite nicely.

For better or worse, the glass axial-lead capacitor package seems to have gone by the wayside. Surface mount chip capacitors have taken their place, and with good reasons (lower lead inductance in particular). While they used to be put onto boards full of TTL DIP packages in the 70's and 80's by the billions for bypassing, the surface mount part is far more appropriate for any use use today I can think of - except your use :-(.

The concept of re-using a surface mount ceramic chip cap is almost laughable. I'm sure it's possible, but it cannot possibly be worth the effort.

If you want them largely for bypass purposes and aren't critical as to exact value, I do see large boxes full of the glass axial caps at hamfests every so often. Often the vendor thinks they're diodes.

Tim.

Saturday night - the stores are closed. The kids have gone to bed, and you finally have time to work on a project.

Oops - need a bunch of bypass caps. Ha! there's an old pci card with plenty of them.

Take two soldering irons and heat both ends simultaneously. In seconds, the cap comes lose with no damage. Check the value on your handy Radio Shack DVM, and sort into the appropriately-marked 35mm film cannister.

Cheers, Mike

Hi Lou,
How about semiconductors? I may be looking for some of the older Motorola
communication ICs, ie., MC4044, 4024
Also, maybe some of the power xistors. MRF 476 etc.

Could you give me an idea if this is the kind of thing you have or are we
talking more semi-complete radios (Motracs etc)?

Thanks!
Bob WB0POQ

Maybe that was my mistake - actually expecting them to meet ratings.

Many caps do behave and I leave them alone, but I've also seen many
fail. I use them, but I am careful of them when repairing.

I was always under the impression that the axial parts had lower inductance,
and thus were superior for bypassing or VHF/UHF applications. Again, leadless
chip capacitors are today's real winner.

Tim.

They're too big. Downright huge by comparison.

I tend to pack my parts very densely when I hand-wire an assembly. I
can usually beat an equivalent surface-mount PCB layout by 50%. :)

Those look like nice parts, but in their case, the "glass" term refers
to the "glass K" dielectric rather than the package. It's not clear
from the data sheet what the package is made from.

For sure I would agree with that - I dont stock every voltage value of electrolytic, so the closest higher voltage gets put into the circuit under repair - or the next higher one if its all I have in stock and it physically fits!. Very occasionally I have to use the original rated component if the design engineer has been a smartarse and not left enough room on the PCB.

One use for tantalums that hasnt been mentioned is for "Audible Power Supply Fault Monitoring" - ie, if the tantalums blow themselves off the board then the power supply is overvolting, if you are quick enough you can see the smoking ruins and know whick rail is kaput.

I make no bones about it, I belong to the "dont use force, get a bigger hammer" school of engineering - if you cant find whats wrong, power it up and see what gets hot!

bama.sbc.edu

Look at the Heathkit Q-multipliers. The QF-1 and HD-11 are the same
circuit except the HD-11 has it's own power supply and the QF-1 taps
it from the radio. You can download the entire manual from that site.

When actually put in a board the axial parts have about 3x the
inductance of the radial parts. You have to include the inductance
of the formed leads, which can't be bent right by the body for the
axials. ISTR measuring about 15nH vs 5nH (but that was a looong
time ago).

This is one of those few areas where I would rather buy than build. A power supply is a relatively simple thing to build, but it can be a real pain collecting the parts. Chances are, by the time you have collected together the necessary stuff, you are going to be in for more money than a high-end commercial supply. And it's not like a rig where building it allows you to tailor the features to what you want. A power supply has a pretty basic job, and it doesn't change. There's always that next neat feature for a rig, so in all probability, you will be buying a new rig in a couple of years (unless you build your rigs, in which case you are probably already working on the next one). A power supply sits there and pumps out 13.8 volts. Ten years from now, you are still going to want it to pump out 13.8 volts.

I would also suggest that 10 amps is a bad size. It sounds like it's going to be the primary station supply, and pretty soon you will need 15 then 20 then 25 ... Somewhere along the line the list will include some junk commercial supplies that will fail in a year or two, likely taking some equipment with them. Of course, if it's for some dedicated application, then a smaller supply is the right answer. But if it's the primary station supply, then going with the smaller supply is almost going to almost guarantee that over 5 or 10 years, you are going to be spending a whole lot of money on supplies, even if you build them.

My advice is to swallow hard and plunk down a pile of change for a 30 to 50 watt Astron. Yeah, it costs more than a VHF rig, but now you're done fooling with supplies for a decade or two. It would probably be quite satisfying building a really nice supply, but unless you are willing to invest years in collecting parts, the cost will be higher than a commercial supply.

If your primary requirement is cheap, however, I'd look into a St. Louis switcher (QRP Homebrewer #6). I wouldn't expect the greatest reliability from this approach, but it sidesteps the parts collection issue, and with a little creativity can probably get you on the air for less money than the caps in a traditional supply. This approach is probably limited to around 12 amps, but it sounds like that would meet your immediate needs.

..

Are you looking for something to use, or to learn about audio filtering?

The Autek QF-1 series of audio filters are very effective, and relatively inexpensive second hand. If you want more performance there are several DSP audio filter boxes on the market. There are also kits available from Ramsay and other sources.

If you want to roll your own, and learn in the process, you have lots of options. Don Lancaster's _Active Filter Cookbook_ has the information you need to create your own active audio filter. Several audio filter articles have appeared over the years in the _ARRL Handbook_, in 73 Magazine, QST, CQ and Ham Radio Magazine.

A $0.49 quad op-amp, a handful of passive components, a couple of potentiometers, a perfboard and an enclosure are about all you need to do it that way.

If you want to get more complicated and spend lots more money you can find a DSP evaluation board from most of the chip manufacturers and do it in software.

And, if you pack a notebook PC along with your Scout, you can always use one of the sound card DSP programs floating around out there.

These are manufactured in such numbers that you can easily buy a
complete supply for less than the cost of the parts. If you want ot
build your own, buy a commercial unit, take it apart, and make your
own design from the parts.

Hosfelt has a 10 amp unit (with a 12 amp surge capability), part #
PSR-10, for $59.
Their paper catalog is better than their web site:
http://www.hosfelt.com/

They also have a nice adjustable 0-20 volt, 10 amp supply (part #
40-173) for $150.

Bob,

Any chance you could send me a copy of that? I'd love to add it to mine.

There are three QF-1A (with simultaneous notch/bandpass or dual bandpass)
on ebay all below $20 right now...

1501. Re: How do you mount LEDs to a chassis?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-03 01:42:12 UTC
From: Chuck <wcmoore@ix.netcom.com>
Message-ID: <aifcnoiqq1@slb3.atl.mindspring.net>
Source record: 42264
Cross-posted to: sci.electronics,sci.electronics.basics,rec.radio.amateur.homebrew,sci.electronics.components

There are commercially manufactured holders for LED's that allow
you to mount the LED to the panel. Determine your LED size. Most
are T1 1/4 (T1.25). Some are slightly larger, some slightly smaller.
Future Active Electronics has the mounts , as well as Allied, Newark,
and other distributors. A bag of 100 usually runs around $10.00.

You will also need to have a drill bit the size recommended by the mount
manufacturer. The mount hole will be a snug fit for the holder. If you
need to remove the LED you slightly compress the holder and the LED/
Holder assembly slips out of the panel. Most holders allow you to insert the
LED from the front of the panel.

There is no rule saying the holder is the only proper way to install the
device but if you are a stickler for commercial appearance then it is about
the most economical way to mount a large number of LED's. If you are
using only a few LED's and you are striving for the high end commercial
then look at the Dialight series of panel mount LED's in mil style holders.

Good luck on your project.

Must we continue this CB operators are evil rubbish?

I've seen idiots on both sides of the fence, and the continued anomisity
from both sides is helping no one. CB is the prime source for new HAMs,
at a time were we need them more than they need us, this kind of
attitude is unwelcome.

Hi,

Welcome!

As the group-title says, this is all about what makes radio communications gear tick and not generally just about the boxes, accessories and the operating thereof that one might expect from a purely CB newsgroup. However, if you are truly interested in the technical side of things, it makes no matter where you get your kicks. Just lurk and put your $0.02 worth in when you feel like it.

Remember, it isn't too difficult to get a basic ham license these days, so why not go for it and join the real fun.

I'd say try one of those Audio switched capacitor filters if you're going to roll your own. They have a tuneable Fo and bandwidth (with Potentiometers),and are real easy to cascade without high percision components. In the old days, the "MF10" by National was in vogue.. I'm sure Maxim or some other chip maker has more modern devices these days. Check out the application notes for whatever chip you find.

Mike,

I think you're sort of right on the return loss bridge. The top part is
an obvious current transformer and the last section is a voltage sample.
Apparently the bottom port is the product of voltage and current or
impedance amplitude. With no phase info, this is somewhat limited in
measurement info, but it gives you a good idea if you are in the ball park
for a match.

Happy Trails,
Steve WB4CZR

Looks good, but you may want to put a overvoltage crowbar on the output (I don't believe many of these supplies include this) as well as a whole lot of transient suppression as a switcher has no line or load regulation for sudden changes. Also, if you plan to use this for 160 Mtrs or lower, you may need some shielding and rfi consideration. If I was setting up a low freq station and was worried about signal sensitivity, I would be using a linear supply. Lots of copper and iron and that's why they're expensive.

==========

There is no product or multiplication. The output is a SUM, either addition
or subtraction depending on the direction of transmission through the box.

I've got a couple of T-217 amplifier assemblies. These originally ran a pair of 4X150's at 50 or so watts output in the 220 - 400 MHz range. They are beautifully constructed (by Collins I believe), and compact, using a servo driven curved tuned line (a little larger than an old fashioned lunch box). I know of a couple of folks that added padding in the form of a couple of small copper straps across the plate end of the line and ran a kW input on the low end of 2M in FM mode. They used the original 4X150A's but increased the air across them.
I also heard of people using them on 432 MHz. Of course if one wanted, 4CX250B's could be directly substituted but I've compared the two data sheets and really don't see any advantage as long as sufficient air is available for the '150's.

One of the units is original with blower and the other is less blower and partially mounted on a 19 inch panel. I doubt if I will ever get around to using these so if there's interest, I'll retrieve them from storage.

I saw a lot of posts that essentially said "don't
build - buy". I built. Cost me $1.97 for an LM317
when I built it. The rest of the parts - line cord,
enclosure, resistors, transformer, pass transistors
etc I scrounged for nothing. The thing is ugly -
but it works great.

Anyway, the circuit I used is simple - collector wrap
around. An example of that technique is seen at:

http://ourworld.compuserve.com/homepages/Bill_Bowden/page12.htm#317pass.gif

The example shown would need to be modified for a 10 amp
supply, by additional pass transistors with emitter
resistors. I'd change the emitter resistor to .1 ohms,
and add two transistors, each with its own .1 ohm emitter
resistor. The three bases and three collectors are
all connected to the same point as the single one shown
in the diagram. Each emitter resistor connects to
a single transistor at one end. The other ends of the
emitter resistors all connect to the junction of the
.3 ohm and .7 ohm resistors and +18 in the diagram.
Essentially, you are adding two transistors and two resistors
to the existing diagram, and changing the value of the existing
emitter resistor from .3 ohms to .1 ohms.

There is another approach, requiring more components:
http://www.rason.org/Projects/powsupply/powsupply.htm

As someone mentioned, parts acquisition can be
difficult. The transistors are easy and cheap, but
you can have some problems getting a big heat sink, capacitors
and transformer without spending a lot. Still, I
have picked up some huge heatsinks at hamfests for
a couple of bucks, and I bought two 12 volt, 10 amp
transformers for $5 each, so it can be done. The years
of scrounging someone mentioned might be on target.

Tnx for your comments.
The device is probably meant for the European consumer marked and
should simplify the construction of an LW/MW receiver (LW=150-300kHz,
MW=550-1560kHz) and such receiver covers the two bands as one.

I am not sure if it will simplify an amateur radio receiver, one
suggestion is a 136kHz RX. It is rather uncertain what the RF-stages
does, is it just an overload protection or does it have gain?
In-/output impedances for the pre-amplifier is not mentioned, nor is
any gain, while the mixer has 10-40k input impedance and 3.5mA/V
forward conductance.
Also difficult to see whether the OSC is an oscillator or just a
buffer for the VCO.
A 135-140khz receiver could be built using a simple VXO on 10564kHz++,
a 10.7MHz ladder filter, and NE612 as product detector, and yet
another wideband FM ceramic filter to stabilize IF amplifier

It seems little point in constructing just another AM receiver using envelope detector as this has, would rather have synchronous detector with TDA1576 or SO41P, possibly SA604, but the latter is really a waste, since TEA6200 has its own AGC detector which could drive an S-meter. TDA1576, SO41P, MC1351P, SN76660N/TBA120, and SA604 may well function as multimode detectors - at least for AM and CW/SSB.

Many thanks Hans,

I see it like a small ham-treasure today! Possebly I will build an RF-bridge
but first Iï¿½m waiting for some special documents to avoid
constuction-mistakes.

What about the expressions "capacitance law: s.l.c" or "linear Type H"?

Iï¿½d prefer a linear or log. capacitor. At what abbreviation have I to look
for??

'Ol George here has spammed most of the Amateur
radio news groups with this garbage.

I guess that he also does not know the difference between
Amateur radio and CB.

George, Amateur radio operators don't need information
on swing kits, echo mikes, roger beeps or any
of the other trash that sells so well to the CB
crowd.

Please peddle your papers over there, OK?

Gary

At least you can put up an antenna. The rules in the city I live in is no Ham or CB antenna more then 12 feet off the ground. For you I would recommend a multi-band vertical but they will cost you. Also perhaps the Yeasu ATAS-100 with the ground plane kit. Good luck and I know what you are going through as I am stuck with all my antennas in the house. I have already had 2 visits from our fines and by-laws department for my city for having a coat hanger 2 meter antenna in a cherry tree.

If it was MY "opinion" being referring to (down below), I gave it. And I stick by it. THAT IS CB JUNK. Amateurs DO NOT as a rule, use it - nor are they allowed to by law....
But then again, neither are the CBers! SO, go as the man said, to the CB group. They'll be a bit more sympathetic to your CB related toys, questions and concerns thereof. THIS is an "Amateur" Radio Newsgroup. Further more, no amateur that runs a decent station needs extra trash to sound good. And they know it! They can be proud of their "STOCK" as the CBers put it - stations.....

Not only am I an Amateur Radio Operator - for many years, but I've been on CB for many years, albeit not much in last couple. I've NEVER had to use such garbage to convey my messages or sound better. So don't even try to hand me the crap about how wonderful it is.

The only reason I've not been on CB is because most of the idiots around here do nothing but fight, yell hello 24/7 or play with their wonderful toys and clog the airwaves. I can find better things to do.

Well, that's prety amazing... my icom radio will 'deadkey' 40 watts on AM. Why would I want a 'swing-kit' to turn it down to 4 watts? Oh, wait a minute. You must be talking about illegal CB mods. Sorry. My mistake. Actually, it was YOUR mistake for posting such nonsense on an amateur radio newsgroup. Go away. Go far away. Don't come back.

There is no reason why you couldn't put up a good dipole antenna anchored in
your tree. If the tree is not close enough to the house, you could simply
put up a good tv antenna mast and anchor your antenna there. I used a
similar set up and could easily talk all over North America on 20 meters.
There are other options as well. Someone has suggested a multi-band
vertical. Many more options are available that what may be obvious. Good
luck.

Your idea of the huge 60' tall yagi is good. It will by far outperform a dipole and will have
a secondary function of being a landmark in your neighborhood. It would also reduce the
problems of BCI/TVI in the area. Go for it!

I had a friend of mine who bought a 220 MHz or 440 kit, can't recall which at moment.

He built it, and it did not work. He brought it to me, I looked at it, couldn't find anything wrong with it so far as his work was concerned. Took it to another friend of ours, a fellow radio tech, he couldn't find fault with the building either. We didn't want to "alter" anything until no other alternative, such as you'll see as you read on.

My friend called Ramsey. They said send it in with $18.95 (if memory serves me correct) and they would go over it. The kit cost him about that to start with! Not wanting to invest more into it, he asked that we look over it some more, this time swapping out components. We did manage to get it to start receiving something, but no where near a useable signal. I'd be a bit leery of them...

In building a kit or a circuit from scratch, especially as a "beginner", a working circuit boosts one's interest and provides pleasure from using it, having been done by one's own hands. However, ONE bad experience can shatter an interest or give you a sour taste and can drive one away. I've seen a few quit after one failure. Even if not their fault. And that is sad.....WE NEED people to be interested in "building" . This hobby has lost "THAT" touch.

On the other hand, in defense of Ramsey, I've built other Ramsey kits and had success with them. So I can not say Ramsey items as a whole are not worth buying. IF you're still intent on buying the kit, ASK about the procedures for troubleshooting, customer service, return, warranty - BEFORE buying. Their policy may have changed since our experience.

You might be better off just listening to it on a scanner! OR buying a cheap used or even a newer 2 meter set up if intent on getting the license. Just don't transmit. Good luck!

Hmmm. "I" replied to the question of the "talk back" boxes and so on - the "toys" that was asked in an otherwise AMATEUR newsgroup. A group not typically known for using such items. Not sure where the antenna stuff came in to play, unless it was the other guy mentioning the CD for sale and pointing out it's having info for 11 meters on it.

However, if your or who's ever it was - CD offers info for both worlds, then might it have been better left unsaid as to which band - but instead, list as - Topics include Antenna building, design, grounding, etc? 160 to 10 meters would have covered 11 meters without singling it out. It may not have come across as a purely CB related CD then. And "I" apologize for this part because I didn't see the CD ad being referred to. At least not the initial ad.

"I" even with all my experience, do not know it all. Nor do I claim to. Even "with" knowledge, things come into play that are unplanned for and must be dealt with. FEW systems are usually installed - bug free.

There are many books and other CDs I'm sure, out there as well, with information for Hams and CBers alike. It's all in how it's advertised. I guess it is just the idea of trying to market something "seemingly" fit to one crowd, in a place where that crowd isn't hanging out.

Good luck with the CD......

>them?

My experience with the Ramsey VHF gear has not been good, and I've read comments from others that seemed to indicate the same. I can, however, highly recommend the TenTec 1220 kit. The instruction manual is extremely detailed, leaving little room for error. You build the kit one section at a time, gaining the theory of operation of that portion, and going through a checklist on the completion of a section. By the time you are finished, you will understand how the radio works, and it most likely WILL work the first try. Mine is running mobile in an SUV and gets plenty of rough treatment, but has performed flawlessly for two years.

If you are in an area with 2m repeater activity, you will do fine with the basic model. (Also fine if you are strapped for funds.) If you need more power, you can order it with a 30W amplifier, or you can add it later.

Also, though 2m is lots of fun, don't neglect your code practice! Have fun while preparing for the next level.

The design of the 440 version was flawed from the start, it just plain didn't work, and Ramsey should refund everyone suckered into buying one, it was pulled from their catalog a couple of years ago.

The 2 meter version worked after a fashion, but a far better design, is the Tentec rig.

Tentec's design has full band digital tuning, pl encode, memory channels, repeater offset and the ability to build in a 30 watt amp (instead of the 5 watt normal version).

I built the Tentec 6 meter version and it worked fine with minimal tuning up, it also had good sensitivity, better than the specs admitted to, power was in the middle of the range that they specified and I had no problems when testing the rig with hams in the area that had less than optimum setups, all of them heard me, and I heard them all.
thanks, John.

Naturally if you could get a big beam up nice and high, that would be fantastic. If your antenna will need to be mounted low, you're probably better off with a vertical and ground radials. Not only will it work more efficiently near ground, it won't radiate as much under the antenna (where your neighbors' TV sets are).

You didn't specify what bands you want to work. I have posted a design for a homebrew vertical that is only 11 feet tall (a little more if you use sloping radials) which works on 20, 15 and 10 meters. It's not exactly "stealth" but it is fairly inexpensive to make. So far two of these have been built that I know of, and performance is roughly equivalent to a quarter wave ground plane on each band. Mine is mounted at 10 meters above ground, but my friend's is mounted directly on the ground, with buried radials.

I built the older Ramsey 2M transceiver (FTR-144) many years ago, and
I did get it to work. But it's no beginners' kit. Tune-up was not as
easy as the manual described, requiring stretch-and-squeeze of several
coils to get the correct drive level for the PA. It performs OK for
local packet operations, which is what I wanted it for. But 5W output
and diode-programmed channels limit its usefulness (compared to what
most hams use). I wouldn't want to have it as my only 2M radio.

Me too. It worked OK for local packet and light use into the local repeater (before they PL'ed it...) but the design had a couple flaws that probably made it marginally legal...something about the way the PLL locked, I forget the details. I built a few other Ramsey kits and they mostly worked, too, but were not great design or quality components. John (?) Ramsey himself used to read these newsgroups and would often dump on anyone who criticised his stuff. I think he (and the company) had some legal problems with the FCC over a couple of the kits he was selling (not that that necessarily has any relevance in this discussion...),

Someone else suggested the Ten-Tec kit. While I don't have any experience with their VHF kits, I've found the othere to be of very high quality. You can also probably find decent used commercial gear for decent prices and you'd likely be better off with it in the long run, compared to Ramsey.

My two cents worth...

It's an AM IF strip. I don't think it was very popular. I have a catalog, but no scanner. I can answer questions however.

Ten-Tec has a great rep, but their 2 meter kit is the same price, with far less features, than the low end rice boxes. In essence, you pay a significant price, feature-wise, in order to build it. The quality of the Yaecommwoods is pretty good, even at the bottom end, so I can't really see where Ten-Tec's quality would be such a big win, either.

Interesting, their web page says you don't have to settle for a stripped down radio, but a quick comparison:

Ten-Tec Icom
$195 $179
15 memories 100 memories
1 nonstandard split 100 nonstandard splits
6 digit LED 6 char alpha LCD custom
display with lots besides
numbers
5 watts 50 watts
plastic front panel steel front panel
- VFO/Memory scan
- PL Scan
PL PL + PL Squelch
Recv 143.5-148.5 Recv 136-174

I'm sure the Yaseau and Kenwood offerings are similar to the Icom, I just happened to have the Icom specs handy. Alinco, ADI and others have slightly lower priced offerings at, some would argue, slightly lower quality.

On the other hand, I have heard that they really treat visitors to their facility well, so if you are planning a trip to Dollywood, a stop by Seiverville might be a worthwhile thing.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 18th 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

If you consider the skin effect.
The skin gets thinner the higher the freq.
So the conductivity of the conductor is less important.
So above say 50 Megs, aluminium may be a better bet than copper since the higher DC resistance causes a thicker skin and therefore lower (relative to cu) hf/vhf "resistance".

I have n't calculated anything but this is just a gut feeling that may relate to the question.

Alan.

Why does anyone care about Litz wire anyway? I can understand this if someone is looking for fine wire that is flexible and small, but other than that, I don't have a clue for the reason. I never used it in the 25 years of rf engineering that I've done except to use it in earpiece assemblies that had to be light in weight. Please! Don't give me the skin effect excuse. This was the original intent, but things got better over the years with winding techiques, core materials, etc.

BTW, don't try to use this wire if you don't have a whole pot full of patience. It is highly springy and usually doesn't solder easily.

Some day, Mankind won't have to put up with RF or liberals; or at least I hope so. :-)

Source record: 42245

The skin depth is inversely proportional to the square root of the conductivity and inversely proportional to the square root of the frequency. So at any frequency at which the wire is at least several skin depths in diameter, the effective resistance is proportional to the square root of the DC resistance. For example, if one wire is twice as conductive as another at DC, it will be 1.414 times as conductive at RF. Copper is 1.77 times as conductive as pure aluminum at D.C., so it's 1.33 times as conductive at any radio frequency, providing the wire is at least several skin depths thick. (The ratio will, of course, be different for alloys.) Aluminum never "catches up" with copper.

Roy Lewallen, W7EL

Yes exactly, and the Icom price was from AES's latest catalog. The 2100H has gone up in price recently as they have switched to a different microphone, a few months ago you could find one for 129.

Compare:

http://www.icomamerica.com/amateur/2mmobile/index.html

with

http://www.tentec.com/Tk1220.htm

for more details.

The other radio on the Icom page, the V8000, is about 279 so quite a bit more money but it's 75 watts, has a front firing speaker, 3 sets of scan edges, 200 channels, and on and on....

1584. ALC voltage on TS-790

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-14 21:21:31 UTC
From: Leif Holmgren <nosmap.sm4rpq@nospam.amsat.org>
Message-ID: <3D5AC9DB.AFD7710B@nospam.amsat.org>
Source record: 42147

Hi All!

I've just built me a new sequencer to protect my preamps and relays when working the 70cm and 23cm bands. I'm really proud of it, fast switching, double security circuits, and It won't steal any part of my CW signals since it uses a digital delay-line. If anyone is interested, I'm working on redrawing my schematics and can send them upon request.

Now to my question.

I tried it out using my kenwood TR-751 and TR-851. The sequencer manouvers the ALC voltage to make sure that even the switch on the fron-panel is disabled when the preamp is connected. The manual does not say anything about the voltage needed but -6.2V Po ~ -30dBm. However, when connected to my fathers TS-790 the ALC circuit does not seem to have any effect. In the manual for the TS-790 there is a line saying "ALC Threshold is about -6V".

How negative must I make the ALC input of the TS-790 to totally disable the power output? Will the circuits in the TR-751 cope with this also, or is there any risk that I will exceed the Ugs limits of some of the FET's that the ALC signal ends at? I have not found any useful data sheets for these transistors on the internet.

With best regards.
Leif / SM4RPQ

Two more sources for litz:
Join the Yahoo the crystal set radio club (bring up
http://www.yahoo.com/ and search for it. Be careful; there are other
groups with similar names - this one has over a thousand posts). Ask
for the wire; I have seen members mention they have small strand count
litz.

If your "small quantity" can be stretched to about a pound, it can be
ordered from a manufacturer such as Kerrigan Lewis in Chicago, IL.
Phone 773-772-7208. They need to set up machinery, so much less than
a pound is impractical, cost-wise. They sell to individuals.

22 gage tinned copper wire can be ordered from Newark Electronics,
www.newark.com stock 02F5296 Except for the $25 minimum, they
are a good company to deal with. Also try small radio stores near
where you live.

Hope this helps,
Jim

> Do you know why Litz wire stops working around 10 MHz and above ?

The many strands in the Litz wire behave like a multi-layer winding, even when you only have one layer of Litz. This means there are high proximity losses unless each strand is much less than one skin depth in diameter. In fact, proximity losses will quickly make the wire **worse** than solid copper as you exceed the critical frequency for the strand size. At 10MHz, the appropriate strand diameter is about 50 AWG (0.0001 inch = 0.025mm diameter), which approaches the practical limit for copper wire. It's hard to make it smaller, and it's all too easy to break strands that small.

So don't waste your money on Litz wire for frequencies above 10MHz. And below that, be sure the strand size is appropriate for the frequency.

I had an order-of-magnitude brain freeze here. 50 AWG is 0.001" = 0.25mm. 0.0001" would be 70 AWG, which would be pretty amazing stuff to see--and you'd have pretty amazing eyes if you COULD see it!

Sorry about that!

This being an amateur radio homebrew NG , we all should encourage people building their own equipment ,taking into account all the requirements for adequate ,safe and RF protected power.
There is no reason not to build a safe and reliable Power Supply Unit from recycled components which will last a lifetime .
But one has to be aware of all the requirements .....and these are ably stated by the various contributions to this NG.

For those building a hefty linear PSU in the 30-50 Amperes range with a big (non-toroidal) transformer ,I would suggest that when fitting the unit in a steel enclosure the transformer iron should be kept away at least 1 inch (25 mm) from the enclosure .
If not there is a risk that the transformer / enclosure acts as a HUM generating transducer (100 or 120 Hz)

Enjoy your homebrew activities.

Frank gm0csz.kn6wh@ntlworld.com

Large quantity of receiving, special purpose & TV tubes priced from $.35 each. E-mail w6krc@arrl.net for a detailed list.

1595. Sanyo 2.4ghz phone frequency

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-15 18:25:51 UTC

Ok, first of all the disclaimer:

*** I AM NOT IN THE USA AND YOUR CORDLESS/CELL PHONE LAWS DO NOT APPLY HERE. ***

Now, on to my question.

I would like to know if anyone has the exact frequencies used by a Sanyo DSS 2.4ghz cordless phone, model CLT-2410 (or similar 40 channel Sanyo phones).

I would like to adapt the plans for a 2.4ghz wireless network colinear antenna I built for my wireless network to my phone and at those high frequencies, a few mhz and a few milimetres does make a big difference.

This BTW is to be used at my fishing shack which is really in the middle of nowhere (lake with 2 houses on it), so interference to others is really not an issue. I am on one side of a lake with no phone or electricity (or roads) and I want to use a cordless base which will be at my sisters across the lake (she has power and phone service). I am already sharing her internet access with a 2.4ghz wireless network we put up and it works perfectly (though sharing a 56 K conection that barely connects at 28.8 at the best of times is a little tedious!).

As it is the cordless phone baaaarely works on the front porch, a decent colinear like we use for the wireless network would be perfect (btw we did try a yagi for the wireless network, worked fine, but with the colinear signal is just as nice AND I can be sitting in my canoe anywhere on the lake and "working" on my laptop while fishing (keeps the boss happy)

1597. FS:Norcal 40 & Cascade SSB kits

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-15 19:32:25 UTC
From: Sasquatch Roadkill <sasquatch_roadkill@NO*SPAMhotmail.com>
Message-ID: <ajgvk7$1an$1@nnrp.atgi.net>
Source record: 42160

All,
Wondering if anyone might be interested in purchasing these two NON-working kits.

Norcal 40 CW rig.
There are no (?) bad solders. I sent it to someone in the Norcal club who looked at it. He got the recieve portion to work, but not the transmit. He suggested that I change out the NE602 (?). I have the manual & schematic for this.

Also have the norcal qrp club Cascade 80/40 meter SSB radio.
After building it I did get it to work (recieve) never tested it on transmit. One night it just did not work after powering it on. Smelled something from inside. Has the manual & schematics and the 40 & 80 meter band plugins.

Ideally, I would keep these and get them working, but they've been sitting in my garage for 5 years. I don't see it happening. These are probably easy fixes for someone more technically inclined. And I need to support my growing camera hobby.

Please send serious offers to sasquatch_roadkill@NO*SPAMhotmail.com
remove the no spam to reply.
If I posted in the wrong NG, my apologies.

HI!

The HP8554B is the 1250 Mhz plug-in. Can anyone tell me what are the output frequencies available from this plug-in when it is used with a HP8444A .5-1300 Mhz Tracking generator. One of them is the first LO output which is the sweeping one (Min. and Max. frequency) Is there a second LO and what frequency. There is a third LO and what frequency. Thanks! Regards! Jos. VE2AUC

1601. Packet Radio to Internet Portal

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-15 23:50:01 UTC
From: The Smith Family <wsbg@sympatico.ca>
Message-ID: <A4X69.5687$%R5.1420783@news20.bellglobal.com>
Source record: 42164

Picture this: an external USR 56k v92 modem connected to the COM port (or tty in Linux) of a box running your favorite BBS package and having it work well as it does right now.
Now picture: an external TNC (sort of like a modem for the air waves) connected to the COM port (or tty in Linux) of a box running your favorite BBS package and have it work well serving not only dial-up phone connections, but connections from Packet Radio (a digital packet transfer ability with Amateur (HAM) Radio.

Both modems can use a com port, both can send signals indicating a connection has been made, and both are fairly similar. There are some things that would have to be added though (easily done) which would be the sending and receiving of "this is my identification letter and number block" which may even be able to be done through IEMSI and have IEMSI log the QSLs (radio identification numbers).

For those of you that don't know IEMSI is a way of programming your terminal program (ie. Terminate!) to automatically negotiate ones name, password, etc. It may not be applicable to your BBS software as it may not yet support it. But don't fret, it's not needed to bring in support for this.

Now for you sysops: Imagine this: You've got a sweet box running your favorite BBS software. It's connected to the Internet, you've got regular modem, and you've got a packet radio modem. Now you can have callers experience your BBS using telnet from anywhere around the world, you've got access for local folk via your phone modem, and you've now got people possibly connecting from areas so far around the world with their radio modems. Wouldn't that be cool. You're last user lister could list people from almost anywhere, and also list their method of connection whether it be by phone, telnet session, or radio modem. It'd be cool, huh? Now for the great stuff. Imagine that BBS software had PPP connect options so that people using HAM Packet Radio Modems or Phone System Modems could get on the internet:

A HAM to Internet portal, oh my! :)

Well if you can make it happen, why not? Try. Try hard.

You can pretty much assume it is in the 2400-2483 MHz band, perhaps toward the lower portion of that frequency range, although the different channels may have some of them in the higher part of the band. For that matter, the Spread Spectrum is probably taking up a large part of the band at the best of times.

At least, according to how they are meant to be in the USA....

This, by the way, is most likely the identical frequency range your 2.4 GHz wireless network is in.

Oh yes, the upper part of this range is overlapped by signals escaping from microwave ovens. They are more or less around 2490 but the frequency control for a microwave oven is crude and they are often down in the band used by wireless telephones and wireless networks.

1st LO swept 2050 to 3300 MHz, used by TG
2nd LO fixed 1500 MHz not taken to outside world, but there is an output
terminated inside, if you see what I mean.
3rd LO 500 MHz fixed, used by TG

From what I remember these are quite tricky to adjust. Both the outputs
you need for the TG are available on the front panel. The TG has it's
own 1.5 GHz Osc. The Opt 59 version also has a built-in 500 MHz osc
for use with the 8555

No, I live in Canada and even RAC is no help. The city is able to make its own by-laws. They just changed the antenna by-law on satellite dishes to permit the Minnie-dish a few months ago. Hell we can't even cut down a tree on our own propriety. The funny thing about it is that the city is looking for Hams to provide emergency communications during an emergency and they have had to go to other municipalities to get them and we have over 400 thousand people in this city. Kind of ridiculous if you ask me.

HV PLATE TRANSFORMER
It is 3000v @ 4 amps 120/220 primaries. It is a heavy rascal though
about 100lbs. I have been trying to sell it have it listed been asking
300.00 for it OBO
time you filtered and rectified should do over 3500v 14" tall x 11 3/4"
wide x 7 1/2" deep
I know it can be shipped probably around 60.00 or so
I just had a transformer sent to me from texas it weighed 110lbs and
shipping was 65.00

Several nice Big Air variables Not really sure about the actual cap of
them but they are big and beefy.

Oil Caps

1-10mf@1500vdc
1- 2mf@5000vdc
4-1mf@2000vdc
2-1mf@3600vdc
2-1mf@600vdc
4- 250mf@450vdc screw in caps computer grade

I have a mobile amp Pride 100 Bi Linear amplifier says 10-80 meters on
the front
has ssb/am preamp

Also Have a 10 METER 2 pill driver amp About 60-75 watts out with a 10
amp 13.8 vdc power supply built in so you could run a mobile in the
house on it.

Collins 300G plate Transformer

1614. Re: how to deal with limited antenna space?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-17 00:58:00 UTC
From: WG <nojunk@mail.com>
Message-ID: <sch79.807$1L4.89549@news1.telusplanet.net>
Source record: 42177

Luckily it is only this city, 44 square miles so I could move and go as high as I like. In your country it is the government of the country that would make the law and has like the cell-phone laws and they are harder to fight then a city council. So I wouldn't call us a socialist country remember the UN rated us higher then the US in being a truly free country. I think the US was down the list at about number 70 and we were in the top 50 of all of the industrial nations. Off topic I know but moving 20 miles to put up an antenna is better then moving out of the country all together. I do think that the law in part will fall for hams as the city knows that they need us. It was enacted in the CB boom years so one more thing we can blame on them. It is not being enforced unless your neighbors complain and mine wanted the tree down so they did what they could. The tree is still up but the antenna is down.

1615. FRS Radios into Ham Radio service?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-17 02:23:36 UTC
From: "Joel (AG4QC)" <joel@cyberbest.com>
Message-ID: <2ti79.2749$Yu.895406194@twister2.starband.net>
Source record: 42178

I noticed the FRS radios are dropping in price so you can now buy them at Sam's for about $50.00/pair. They operate in the 462-467MHZ range and some even have CTSS codes. I was just thinking they are only about 20MHZ or so from the ham band and wondering if anyone had any experiences with conversion.

Joe Loucka AG4QC

1616. Quad FET?

A question on behalf of a friend.

He asks:

I'm wondering if anyone makes a quad FET like the old Siliconix Si8909
anymore. That was designed as an active balanced mixer, that could make
a front end about as immune to overload as you could possibly imagine.

Appreciate any thoughts.

Well, it sounds like the best move is to sign up and then advise them
on the issue. Then you can work on getting it over-turned. I hadn't
done anything that grand, I have found that one person who acts DOES
make a difference.

The Fairchild FST3125 bus-switch tends to be used for high-performance
mixers these days. A properly designed mixer using one of these is about as
good as you can get; you start running into non-linearity problems with
other parts of the system, like the IF filter. I've designed a mixer PCB
using one of these, but haven't got round to making it, yet. I'm using a
circuit from RadCom, which you will find here:

most of the world uses metric system , USA uses the imperial system ,just
as easily we could have used a different system to count frequency.
Think about it , we're so used to 0-9 to count , measure ,anything.Its hard
to think outside this.
it was developed by asian/indian culture, because of the number of fingers
on both hands.
could you Imagine a radio frequency with a hex readout ?

it could have been worst that the chinese alphabet (5000 to understand 95%
of what out there, 60,000 to cover everything)
counting to infinity a new symbol for each count progression

We make the frequency count fit into our way of counting, base10 , but can
frequency find a harmonius or perfect counting system?

Hi Guys,
I've listed on EBay a set of new and unused chassis punches. There are eleven punches, ranging in size from 1/2 inch to 1-1/2 inch, including a 1 inch square punch. I paid $200+ for them, but they're not attracting much interest and looks like I could get taken to the cleaners. I'm trying to drum up some interest, so if you're a homebrewer, check these out!

I've not, but then again it's not something I would choose to
bother with for multiple reasons. Mainly the fact that, with most FRS
radios, their innards are not what I would call "quality" (remember,
they're a mass-produced item, made to sell as cheaply and as quickly as
possible to as many people as possible).

I would also be concerned about their long-term reliability.
Another thing to remember is that they don't put out more than a couple
hundred milliwatts. That makes them pretty much useless for anything
other than their designed purpose.

I really think you'd be better off scaring up some retired Motorola
portables at a ham swap, and putting them on your frequency of choice.

1626. Tayloe detector again

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-17 16:58:05 UTC
From: bpasaric@mac.com
Message-ID: <1fh2nc4.v96a5213if6fcN%bpasaric@mac.com>
Source record: 42189

In the QEX for July-August there are two interesting articles about the Tayloe receiver. The first one is "Dirodyne: A New Radio Architecture?" written by Rod Green, VK6KRG. The second one is "Software-Defined Radio for Masses" Part 1 - written by Gerald Youngblood, AC5OG.

In fact the Tayloe detector is a bi-directional device: if you go from left to the right, you will get an SSB receiver; if you go from right to the left, you will get an SSB exciter. In order to avoid the audio phaseshift network (APN) Rod Green connects the two Tayloe detectors back-to back and in the output he gets an IF SSB signal at the standard 453 kHz IF, which then goes to the third mixer. The performance numbers he has achieved are quite impressive, although there is some more noise - probably because of the three mixers in a chain.

The second article is going to describe a complete transciever (for masses!) using a PC sound card and some software - used instead of the APN (there will be three more articles).

It seems to me that the main idea in both the articles was how to avoid the APN which consists of 24 1% resistors and 24 5% capacitors. I made a Tayloe receiver myself a few months ago, and making a good APN was no problem. After all, they could be factory-made and brought to the market with even higher quality. The greatest problem I had was soldering the demultiplexer 3253 to the PCB, because they are all of the SMD type, which exhausted my nerves - although I was working with a magnifying glass and a micro soldering iron (I'm 70 now). Also, it was not easy to find those chips and get them. Besides that, in my opinion even a beginner could make the Tayloe receiver if he had a ready made PCB with a 3253 on it, or a kit with a ready APN.

I would also like to draw your attention to an article published in the British SPRAT No. 101. That is Jan Verduyn's "An Experimantal DC Receiver". He successfully uses a VFO with two times the input frequency (insted of four times) which is a great simplification and help for homebrewers.

Anyhow, Tayloe has hiven a lot if stimulation for new ideas and experiments which are revealing and enlightening. No doubt, Tayloe is my choice.

Any experience so far, or comments?
Bozidar, 9A2HL

There is a european version of FRS which opeates in the 70CM band. You might want to look for those radios. However they are likely to be simplex only like our FRS.

sadly the EU version (PMR446 in UK) operates on 8 channels at a
frequency between 446.0 and 446.5 iirc, our UHF band is 430-440 Mhz.
As for mods to bring them onto our frequencies.. none I've found.

1629. Re: FRS Radios into Ham Radio service?

Source record: 42192

In the US, the band plan for 445.00-447.00 is "Shared by auxiliary and control links, repeaters and simplex (local option)" with 446.00 being the "National simplex frequency"

Sounds like they'd fit right in in the US - for licensed operation. I did see where someone has a proposal in front of the FCC to make those frequencies available for visitors. I kinda doubt if it will fly.

1630. RFI from unknown device

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-17 21:20:47 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <ultfgbfoajh2ac@corp.supernews.com>
Source record: 42193

Something in the neighborhood has started producing RFI birdies every 60.074 kHz in the upper HF region (at least 20 to 29 MHz). The birdies appear not to be harmonics of the spacing and appear to be weakly modulated at about 130 Hz (which could be 120 Hz).

The birdies are not all of equal strength, but some are S4. The duty cycle seems to be 24/7.

What sort of device should I be looking for?
Thanks, Mac N8TT

I've bought a PMR446 radio and could 'open' it have modified it to cover
the entire UHF band (420-470Mhz). As far as I know it is the only PMR446
modifyable this way. The radio is a 'Team Tecom'. The mod allows to
switch between the PMR mode, LPD mode and HAM mode. It can transmit with
0.5W power and has a SMA antenna connector.
It is really small and works fine on four AAA-cells.

Here a link with a picture:
http://www.thunderpole.co.uk/tecom.htm

The PMR frequencies are the following:
Channel 1 - 446.00625
Channel 2 - 446.01875
Channel 3 - 446.03125
Channel 4 - 446.04375
Channel 5 - 446.05625
Channel 6 - 446.06875
Channel 7 - 446.08125
Channel 8 - 446.09375

The city is Vancouver BC of cores. The same city that was the first to ban
smoking in doors in restaurants and the like. Also the same city that ban
the use of radio control planes and gliders and has tried the same ban with

Sounds like it's time to overthrow your representative form of
government and replace it with a dictatorship. Just be careful choosing
your dictator. . .

does anyone know if the maxar 80 , 800mhz crystal rig can be converted
for 900 ham use ?

have 4 of these in good working order and want to use them as link
txcvr for my repeater system if they can be converted fairly easily.
the shift is pretty far, almost 100 megs. so if it's not feasable,
i'll just have to sell them off.

also, does anyone have a pa for the ge mastr exec lowband mobile ?

kinda roasted the one i had and would like to replace it fairly
cheaply =]

thanks for your time

Hello all,

Without taking too much time here, I have designed a one transistor FM receiver. I call it the 'Radio Shack Special', since all of the parts may be purchased there, except for the variable capacitor, which can be skinned a different way!

Philip from Florida just got thru making it and was astouded. I know, I was astounded too when I completed my design...sensitivity...selectivity... and great audio output is what you will get with the simple one transistor MPF102. Yes, IT MUST BE AN MPF102. I have experimented with this transistor for nearly one year and have to it done pat!

So, without further ado...go to my website and scrool down 'till you see 'The Radio Shack Special Project', and then read what Pedro, Dick and Philip had to say about it too...just don't take my words.

I thank you for your time and surrender this project to anyone who loves simple and yet, dynamic endings!

My website is at: http://braincambre500.freeservers.com

a friend, Patrick

Source record: 42105

One of my pet topics!

Hello Zed and the group,

In article <M6q79.26383$dr.5100984@e3500-atl1.usenetserver.com>, Zed
<G@G.com> writes
>most of the world uses metric system , USA uses the imperial system ,just
>as easily we could have used a different system to count frequency.

The metric system and the decimal system are two different things. The
metric system is a decimal system, yes, but decimal is used in parts of
the imperial system (tenths/hundredths/thousandths of an inch, and I
think there are ten US pints in a gallon - in the UK we have eight
pints).

>Think about it , we're so used to 0-9 to count , measure ,anything.Its hard
>to think outside this.
> it was developed by asian/indian culture, because of the number of fingers
>on both hands.

It's an unfortunate choice. The value of a numbering system increases
with the number of factors.

10 - halfs, fifths, tenths three
12 - halfs, thirds, quarters, sixths, twelfths five
16 - halfs, quarters, eighths, sixteenths four

Looks like base twelve gives best value, and we only have to invent two
new symbols.

>could you Imagine a radio frequency with a hex readout ?

Not easily, but I was taught to count in tens, to my disadvantage. Years
ago when I programmed the Z80 without an assembler I could do hex
addition and subtraction in my head for calculating jumps, so I expect I
could learn. I have an uncomfortable feeling, though, that once I'd read
the display I'd be converting it back into decimal.
>
>We make the frequency count fit into our way of counting, base10 , but can
>frequency find a harmonius or perfect counting system?
>
Binary might be good. Doubling the frequency just shifts everything to
the left one notch. The display could be very cheap too. 25 LEDs cover
from DC to the top of HF (33,554,431 Hz) with 1 Hz resolution. 28 LEDs
in four 7-segment displays only go to 9,999 Hz.

Any other suggestions?

John G4EDX

Source record: 42107

For the record, we also have 8 pints to a gallon. But our pints are 16 ounces instead of 20. Our ounces are the same size as yours, so the net result is that our pints, quarts, and gallons are 4/5 the size of the imperial versions. Here, a "pint's a pound, the world around" (pint of water, that is). There, a "pint of water weighs a pound and a quarter".

Once again, my hat's off to our neigbors to the north. Canada did the conversion to metric, and did it right.

I have been looking for another project for a bit and stumbled on a construction project in the '99 Handbook. The article details an accurate directional wattmeter and is on page 22.36. Both this circuit and one in a Feb '90 QST article (A Simple and Accurate QRP Directional Wattmeter) use a post-detector correction circuit to substantially improve low power and swr accuracy. Ultimately, I'm wondering if I can use the detector circuit in the venerable and nearly ubiquitous heathkit hf swr/wattmeter (hm-102) as a core for an enhanced accuracy meter. Now the first broad question - can this correction be done in software (got a sleeve of 8051's to use up!). Is there a wattmeter guru out there who can get me started ?? Thanks in advance.

I've recently programmed a 42-50 Mhz Motorola Maxtrac to the 6M amateur band. I used the modification on the "Batlabs" page, adding some solder to get it to transmit beyond 50 Mhz. It helped, but only to the point where I can get full output to about 51.6 mhz. Beyond that, the power folds back to about 20W. Does anyone know of any modifications that can be done to extend the coverage by another 1 Meg or so? How about any other web sites that discuss the issue? Please, if you can help, drop me an E mail at njscan@lycos.com Mt ISP is having issues with USENET so I can't always access it. Thanks

No, eight pints per gallon in the US. 16 fluid ounces per pint, which
means a pint's a pound at standard temperature and pressure.

You left out
60 - halfs, thirds, quarters, fifths, sixths, eighths, tenths, twelfths,
fifteenths, twentieths, thirtieths, sixtieths.
And we already have experience with 60,-- time and angles.

Interestingly enough, for some things that officialdom obviously feels important, we regress to imperial. Example is whenever some individual is wanted by the police their height and weight are almost invariably given in imperial rather than metric - at least in Ontario.

I also find it surprising that my grandkids and the kid who cuts my grass are very comfortable with imperial, although they have some difficulty using a dial phone or telling time from an analog clock.

I also find it amazing that Hams would want to use anything other than metric.

NASA tried to go all metric, but their suppliers balked. So they
give dimensions in both systems in their contract proposals.
That doesn't pose any problems as long as a supplier works
consistently in one set of units or the other. Where things
can get nasty is if they transpose one set of units for the other
when communicating with each other. That has happened.

Number system has nothing to do with accuracy (or lack of it).
A given number (at least integer) is identical in ANY number system.
Note that many frequency counters use a different number system to count
than they use to display. Apparently I'm missing the point of the original
question.

Don't know about the Aztecs, but the Babylonians used
base 60. That's why there are 60 seconds to the minute
and 60 minutes to the hour, also 360 degrees in a circle.
They were the first systematic astronomers (astrologers)
and needed convenient ways to keep track of time and
angles. Having a lot of whole number divisors made their
calculations easier. (The decimal point and zero hadn't
been invented yet. The arabs did that later.)

Bob -

Although you can program many commercial radios for the amateur frequencies, I have found that an "alignment" of the radio for the new frequency coverage - is often desirable. This is especially true of the 30-50 MHz (low band VHF) and some 150-174 MHz (high band VHF) radios.

This is specifically covered under the "Hard Fix" section low band VHF Maxtrac radios moved to 6 meters.
http://www.batlabs.com/6mmax.html

If you don't have the equipment (dummy load, RF wattmeter - Bird, signal generator), a Motorola shop can make these adjustments (Receive sensitivity and TX output) in an hour or less. A Cushman would be handy for this adjustment.

According to "Soft Tempest: Hidden Data Transmission Using
Electromagnetic" <http://www.cl.cam.ac.uk/~mgk25/ih98-tempest.pdf> by
Kahn and Anderson, I wouldn't bet on it. The LCD in a laptop generated
a easier to read signal than a traditional CRT monitors. I interpreat
the clearer reception as meaning a stronger signal.

I don't see any reason it couldn't be done with software. The whole scheme is very temperature sensitive, though, so you'd have to restrict operation to a fairly narrow temperature range or sense the temperature and compensate.

As it is, the correction used in the QRP wattmeter, at least, isn't exact -- the DC correction only approximates the AC error. It does, however, correct well enough to give very good accuracy. But it would be possible in theory to do even better with software.

You'll find useful equations in the original QST article in the February 1990 issue, but don't depend on them for determining temperature compensation. Temperature is explicitly shown in the equation relating diode voltage and current. But what isn't usually shown is that the saturation current Is is temperature dependent and that dependency usually dominates the overall temperature characteristics.

If nothing else, the project should give you a good introduction to solid state physics if you're not already acquainted with it.

Roy Lewallen, W7EL

Original question -- guess it is good as any??

To the hex proposer -- If the creator wanted us to count in hexadecimal he would have given us sixteen fingers. That is fingers 0 thru 9 and fingers Alpha thru Fox --- hmmmm

73 in Hex is 115 for the one who asked -- and he/she was probably kidding.

Then again 73 + 88 = 161 (seen that one yet on your QSL card or on CW ???

And in CB it is passing the good numbers - slowly invading the Ham bands along with the "first personal is"
All in good (number) fun.

Yeah, international standardisation of measurements, currencies, company accounts, languages, is a matter of economics, saving of labour and a reduction of friction.

It's a long tedious process. It takes at least two human generations to achieve any significant improvement. And then only after determined agreed international effort.

Something must be done to find room on this tiny overpopulated, polluted environment, dangerous Earth. Otherwise the basic animal instincts of survival of the fittest will find their own solutions.

Is this what everybody wants? Are we to follow the dinasaurs? Should we search for another uninhabited planet somewhere else in the Galaxy and pollute that?

Or should we relax and safe-sex masturbate in front of 24-hour pornography on the TV and wait for the inevitable?
